STATE LIBRARY.

Extract from the Political Code.

SECTION 2296. Books may be taken from the Library by the MEMBERS OF THE LEGISLATURE, DURING THE SESSIONS THEREOF, and by other State officers at any time.

SEC. 2298. The Controller, if notified by the Librarian that any officer has failed to return books taken by him within the time prescribed by the Rules, and after demand made, must not draw his warrant for the salary of such officer until the return is made, or three times the value of the books, or of any injuries thereto, has been paid to the Librarian.

SEC. 2299. Every person who injures or fails to return any book taken is liable to the Librarian in three times the value thereof.

No person shall take or detain from the General Library more than two volumes at any one time, or for a longer period than two weeks. BOOKS OF REFERENCE SHALL NOT BE TAKEN FROM THE LIBRARY AT ANY TIME.—[Extract from the Rules.

☞The foregoing Regulations will be strictly enforced.☜

MINING AND SCIENTIFIC PRESS.

An Illustrated Journal of Mining, Popular Science and General News.

BY DEWEY & CO., Publishers. SAN FRANCISCO, SATURDAY, JANUARY 4, 1879. VOLUME XXXVIII Number 1.

A Practical Traction Engine.

[Written for the PRESS.]

The subject of transportation by means of the road-locomotive, or traction-engine as it is called, has occupied the attention of engineers in all parts of the world. It is believed that California has produced a machine that stands among the best forms of the road-locomotive; from late tests it appears to be one of the most practicable engines of this class that has ever been introduced.

The accompanying engraving represents one of these machines, on three wheels, all of which are propelled hy beveled gearing.

The following are the principal dimensions: Boiler—length over all, 10 feet; boiler, diameter of shell, 48 inches; boiler, thickness of shell, ¼ inch; boiler, fire box sheets, ⅜ inch; load on driving wheels, 2,300 pounds; steam cylinders, diameter, 8 inches; stroke of pistons, 12 iuches; revolutions of crank to one of driving wheels, 10; driving wheels, diameter 72 inches; driving wheels, breadth of tire, 12 inches.

The boiler is a new and peculiar multitubular arrangement, which makes steam as fast as required, from a comparatively small amonnt of water, doing away with considerable bulk and weight. There are two engines mounted on top of the boiler; the crank-shafts are coupled and the cranks are set quartering to avoid the possibility of ever stopping on tho center; the bed plates have the cross-head guides cast solid with the bed; and the cyiinders are secured in sliding hearings fastened by flanges to boiler-brackets; hy this means the expansion and contraction of the hoiler is accommodated, avoiding a considerable strain on the engines. The driving-gears or angle-shafts, are on each side of the machine as shown, and are driven by the beveled pinions on each end of the engine shaft. The angle-shafts ruu in angle bracket-boxes, so that one pair of shafts having beveled pinions run the forward wheel-gears, and the other pair of angle-shafts also have heveled pinions that drive beveled wheels sccured to the rear traction wheels. The forward driving gears are keyed to the outer ends of the forward axle, or driving shaft, more properly speaking, as the latter drives the forward or steering wheel, but at the same time allowing it to be moved in au arc of a circle sideways at any angle desired for steering the machines. This is accomplished by means of a ball and socket joint in tbe huh of this wheel.

This ball and socket joint is the most ingenious part of the whole machine, and to accomplish the work of driving the wheel in all positions, a numher of steel keys are fitted in the ball, aud projecting to work in slots cut in the shell or casing of the ball.

This casing has projecting faces with revolving rings on each side of the wheel, and to these rings are bolted arms on each side running back to a gear segment, operated by a pinion on the end of an upright spindle or shaft with a hand-wheel at the top, just in front of the steersman's seat; here the man piloting the machine has control of the throttle valve and reverse lever.

This is the first instance in which the steering wheel has been made to propel tbe machine; and it can be made to do the work independent of the bind wheels, in case of necessity; as for instance when both hind wheels become mired, or get into quicksand, or deep ruts in the road. This is accomplished by having self-adjustable clutches on the hind wheel shaft, also for backing, etc.

In all of the traction engines heretofore built, only two wheels have been employed to propel the machine, but in this invention all of the wheels on which it runs are traction wheels, and more than three may be employed if desired. This machiue was used for a considerable length of time in the State of Nevada, hauling ore and other freight from mines to mills, etc., running up mountainous roads (where mule teams had been used); the grade being in some instances 530 feet to the mile, and hauling ten tons on wagons at a speed of two and one-half miles per hour. After working for one company until tbeir mines gave out, the machine was brought to Sacramento, where it was employed in house moving and other heavy work.

The Sacramento Wood Co. have recently bought a Pacific coast interest in this invention, and have put the machine to a very severe test, showing its ability to haul heavy freight in a successful manner. Capt. J. Roberts, the leading spirit of the company, took this machine up the Sacramento river on one of their steamers, and landing in Colusa county, where they run regular trips back into the country, a distaace of 16 miles, taking freight from the steamer, and bringiug wheat back, they loaded six Bain header wagons with 300 sacks of grain, also hauling one extra Bain beader wagon contaiuing a tank in which they took 615 gallons of water, besides 1½ tons of coal, making over 24 tons total freight in wagons; tbe machine also carried tanks secured at each side of the hoiler, these bolding 250 gallons of water. Five miles of the road was very dusty, and full of ruts, we had several sloughs to cross, making a very severe test of the traction power of the machine. But if the roads are level, hard and free from ruts, the machine is capable of hauling 35 tons at a speed of three miles per hour.

The machine works admirably as to pulling or traction qualities. The machine weighed on the scales—having steam up and 250 gallous of water in the tanks, also coal in the cab—11½ tons total weight.

Capt. Roberts' Company has plenty of work for a large number of these machines, as they haul freight from various points throughout the Sacramento and San Joaquin valleys to their steamboats and barges on the rivers.

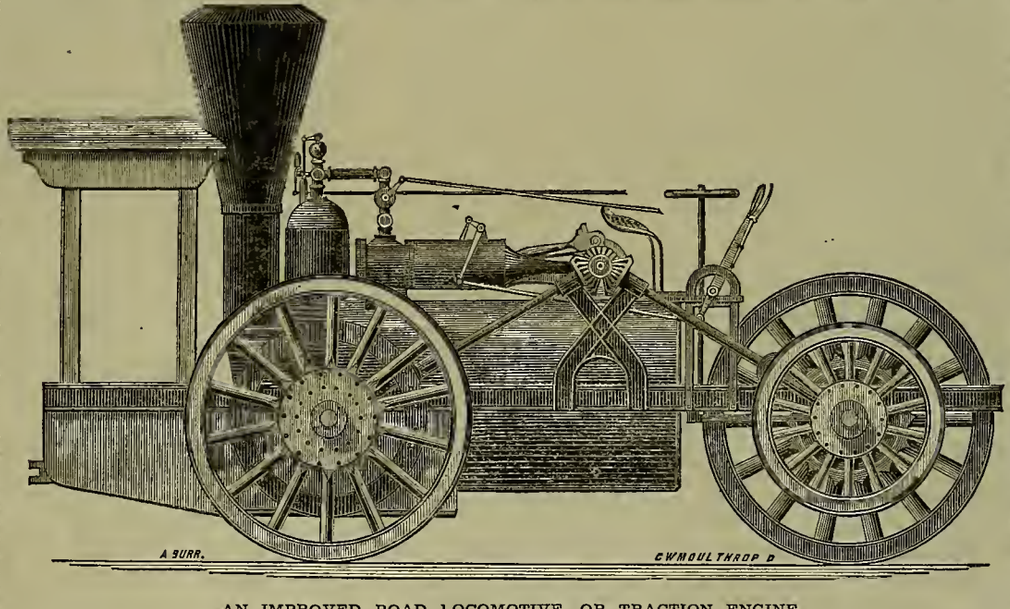
This traction engine will run over any kind of ground; it can enter any farmer's field, plow his ground, and at the proper time haul away his grain or other freight, running in any direction without reference to depots or tracks that at present are so necessary for tbe transportation business of the country.

From the recent trial of this engine, the constructing engineer deduced tbe following conclusions: A traction engine, or road locomotive, may be constructed upon this plan, so as to be easily and rapidly manœuvred, hauling a long line of freight wagons on the ordinary roads, and turning without difficulty on a circle such as are common at all cross-roads.

A locomotive weighing six tons is capable of haubng 25,000 pounds up a grade of 525 feet to the mile at a speed of 3½ miles an hour. The traction-power of the machine tested was eqnal to 30 horses.

The coefficient of traction was shown to be about 0.5; the weight that could be drawn on a perfectly smooth and level road was 175,000 pounds; this is exclusive of the weight of the engine, and the amount of fuel required is estimated at 500 pounds a day. In handling the machine the most experienced and skillful men are required. The difference between the performances of the same engine in different hands was 12%.

It is estimated that the expense in heavy hauling hy steam is 25% less than the cost of horse-power on an ordinary road. A much larger and more powerful machine is now being built for the company by Root, Neilsou & Co., Sacramento. The inventor is Mr. R. R. Doan, who commenced many years ago to study the problem of substituting steam power for auimal power on the highways and for farm use. After years of toil and the expenditure of a large amount of money, buildiug the machine in several styles, he has profited by the experience, and we believe that he has accomplished the desired result, in the road locomotive represented by our engraving. C. W. M.



AN IMPROVED ROAD LOCOMOTIVE, OR TRACTION ENGINE.

The Bodie Claims.

The Bodie mines were taken up under United States law, and held as from the United States. But now it transpires that tho United States did not own the land occupied by many of the chief mines; on the contrary, the State owned them, and the United States could not allow any one to hold them either by yearly work or by purchase—in fact, bad no claim on them whatever. The State owns the 16th and 36th sections of every township. She was granted them for school purposes. Owning them she has a right to sell them. This she has done in the preseut case, and there was no stay in her proceedings, because the 16th section of one township contained some of Bodie's richest mines. The plat of survey of the land in question was filed on March 16th, 1878. At that time those who were located on the 16th section might have known how they were situated. From that date they were allowed the refnsal of the land for six months. Those six months have passed. The locators bave not purchased from the State. Others have taken advantage of this negligence, and bave bought the land and hold a State title to it. The title seems to be good, and all that Bodie can do is to compromise. The interested mines are: Bodie, South Bodie, South Standard, Red Cloud Consolidated, Belvidere, Bodie Tunnel and Mining Company, Summit, White Cloud, Goodshaw, Aurora Tunnel, Maybelle, Concordia, Noonday, Richelieu, Champion, Sigourney, Mono, Mono and Cross Consolidated, Bodie Hydraulic, Lady Alice Tunnel and Mining Company, Relief Consolidated, South Bulwer, part of the Bulwer Rustler, Dudley, Requizon, Republic, Booker, Humboldt, Double Standard, Jupiter, Glynn, Daily, South Belvidere, and the placer claims of Wm. Irwin, Johu F. Boyd, G. S. Morton and others. The South Bulwer has compromised.

Bodie stock has been surprisingly low for some weeks past. It has exhibited a deadness which grew, perhaps, out of some premonition, if not positive knowledge, of this trouble. It will be a great pity if this flourishing town is to receive a set back here on the very threshold of so promising a career. Mining towns in the first few years of their growth are particularly liable to such disorders. But perhaps none other ever received such an aggravating blow as this that has been dealt Bodie.

BOSWELL FRUIT DRIER.—We call attention to the advertisement of the Boswell heater oompany on page 16 of this issue. The principle of deflected heat as applied to drying fruit seems to he worthy the attention of all interested in that branch of industry. The combined apparatus for cooking, baking, beating, drying, etc., is a great auxilliary to the economy of housekeeping, and the apparatus is also claimed to he the most economical as well as the best arrangement for drying fruit, etc., that is now before the public. Mr. E. L. Sullivan, an old and well-known citizen of the State, is at the head of the company.

THE Salt River *Herald* says: Messrs. I. N. Cohen & Co. have received 30,000 pounds of copper from the Longfellow oompany during the past week; shipping 20,000 to the railroad dnring tbe same time.

WORK progresses favorably at the Black Jack, Idaho.

PACIFIC COAST POSTAL CHANGES.—Following are the postal changes for the week ending Dec. 29th: Offices Established—Novelty, Kings county, Washington Territory, George B. Boyce, Postmaster. Asbley, Wasatch county, Utah, Wm. H. Wallis, Postmaster. Offices Discontinued—Laplays, San Luis Obispo county, California. Name Changed—Willow Forks, Umatilla county, Oregon, to Pettysville. Postmasters Appointed—Charles Crandall, Altoona, Trinity county; Karl H. Plate, Tyrone, Sonoma county, California. Henry Williams, Sweetwater, Esmeralda county, Nevada. David Sommers, Summersville, Union county; Josbua Pullen, Zion, Clackamas county, Oregon. Samuel Egesley, Silver Spring, Salt Lake county, Utah.

THE Little Emma, Democrat mountain, Colorado, was discovered in May, 1877. It has since produced $22,853.09 net.

THE Tiptop company, at their mill, Gillett, are producing silvor bullion at the rate of $50,000 a month.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

Scenes in the High Sierra Back of Yosemite—Continued.

[Written for the PRESS by J. G. LEMMON.]

No. 2. Mount Lyell and its Glaciers.

"Who has not heard of the lofty Lyell group of peaks, and of their system of still living glaciers?" The dignified Prof. Whitney has ably described them in the cold exact terms of science, and the Bonny Scot, Johnny Muir, has set them forth in warm, glowing language, that is just as truthful, and ten times more readable for the average mind. "Who would not visit them from a distance, if able, especially, who would not make a desperate effort if he happened to be in sight of the glistening pinnacles, even though his back was nearly broken?" Thus I reasoned as I looked off from the dizzy crown of *Tis-sa-ack*, and studied the approaches to the wondrous group lying about 20 miles distant, as the bird flies, but with many miles of bald ridges and tortuous, wooded, dark valleys between. But resolution and ability were not in accord this time. The next morning I was unable to saddle my horse, and the next after, found me too weak to venture the chances of a toilsome, dangerous excursion, especially as I was alone. But to acquire strength I moved painfully about the woods near Anderson's cabin, securing among other rare plants, the *Bolandra Californica*, Gray, the type of a genus composed of a single species, and dedicated to Prof. Bolander, who, with the founder of the genus, are the only botanists that are reported to have met with the plant. The curious plants belongs to the saxifrages, very singularly combining in itself the charactere of four or five of the genera.

Another striking plant growing here in a grassy bog, was discovered by Bolander, in the Mariposa station meadows, and named by him *Senecia Clarkianus*, in honor of Galen Clark, the genial pioneer of this region, and the present guardian of Yosemite valley.

The third morning found me on the Mono trail leading my burdened horse up the pass to Cathedral valley. The trail was in places obliterated by roving bands of sheep, causing much delay in searching for it, for attempting to proceed by any other way was fruitless. It was late in the eve when, after treading the long valley skirting the curious Cathedral, crossing spurs and winding around glacier lakes, I began to descend into a deep and broad valley, upon the farther side of which a column of smoke beaconed the way to Soda spring and to Lambert's cabin, a warm supper and a rude couch—the latter all too poorly supplied with blankets for my weak, dispirited condition.

The Tuolumne meadows carpet the floor of the deep, even-sided nearly straight valley of the upper Tuolumne, for a space of eight or ten miles long by a half to a mile wide.

This valley is the track, the wallowing trail of an immense glacier of the olden times, and every tough, rounded rock appearing on the floor or sides, shows the grinding action of the crawling monster, many of the silicious rocks shining like glass.

Avalanches.

The sides of the valley are clothed with the luxuriant *Pinus contorta* (miscalled "Tamarack"), save where broad gaps of one-half to a mile, show where from the snow-gathering crests along the lofty rim avalanches of snow and rocks thundered down, carrying the forest with them out into the valley. Some of the avalanches occurred at recent date, how recent might be easily approximated by cutting trees upspringing in their track and counting their rings of annual growth. Others cleared the timber off their pre-emption so long ago that the forest is nearly restored, but the precise width and comparative violence of the slide can be determined by noting the hummocks of rocks and earth lying in interrupted bands along the center of the valley—telling where decayed the upturn trees.

Above Soda spring a mile or two, the Tuolumne river, clear, cold and singularly destitute of fish, divides into two branches. The east branch comes from circling around the bases of Mounts Dana and Gibbs, 11 miles distant; the south branch, called Lyell Fork, comes gliding along a valley similar to the meadows, but with still more interesting evidences of snow and rock-slides. At the south end the walls close in and the water comes from two sources, cascading down a precipice half a mile high. Leaving my faithful Stanley here securely tethered with a long rope where he could eat and drink at will, I prepared to climb the precipice in the early morning of a fine August day. The vicissitudes of a long, perilous exploration had endeared us to each other, and it was with poignant sorrow that I shouted in reply to his neighing entreaties sent lovingly after me as I clambered up the precipice.

Climbing Mt. Lyell.

As I neared the top of this precipice, I looked expectantly for the peaks of Lyell, only to find a broad, bush-covered bench, back of which a mile away, rose another precipice a half mile high. Climbing wearily up this, aided by the spirea and gooseberry shrubs clinging to the crevices of the rocks, I was encouraged by a most enchanting view of the peaks five miles away. Between lay an alpine plateau, destitute of trees, covered as late as July with snow, now partially exposed, revealing dozens of small placid emerald lakes imbedded in steep grassy banks, brilliant with rare flowers and butterflies.

The lakes with all their decorations were arranged in lines, between which rose long ridges of snow. Mounting one of these, I saw that they led back a mile to still another precipice, on the brow of which loomed the rounded, front-face of a semi-circular moraine. The region of living glaciers was near, and joyfully I hurried over snow ridges and around lakes, only occasionally snatching a flower and crowding it into my portfolio, or pinning a butterfly to my hat. I must not stop to study these wonderful phenomena now, for the noontide sun is shining hot, and the grand arcana is but entered.

"Will precipices never end," I exclaimed while pulling myself up the slippery, moss-grown rocks by laying hold of clumps of *Bryanthus Breweri*, prettiest of California heathers, so charming that I must be pardoned for stopping to observe. One bluff several hundred feet in extent, was all ablaze with crimson and orange, the blended colors of this heather and another exquisite relative, *Cassiope Mertensiana*.

At last I encountered the sharp, steep-piled rocks of the moraine. Twice in my eagerness to get up, I displaced rocks and with them tumbled to the bottom. When at length I reached the crest, tired, bruised and torn, *a scene appeared that stirred my being to its very depths!* A still, azure lake, its farther shore being filled in with a vast semi-circle of angular rocks, which was curled around the front of an immense precipice of solid blue ice 40 feet high, and reaching from wall to wall of the canyon, its steel-blue upper edge along its entire rainbow curve burdened at intervals with toppling rocks, some of them as large as dwelling houses, while beyond and over all towered the snow-striped pinnacles of Lyell.

I could not shout this time, for I was thinking of far-away friends. I could only murmur the names of each and fervently wish them there at that supreme hour!

But we must not linger here. Other startling phenomena are at hand, and we will try to study them in proper connection at the close. Now, our business is climbing. We are yet to surmount formidable and unexpected difficulties.

Turning the flank of this barrier I was soon on the back of the glacier. The snow of several seasons lies on the top, blown by the wind into ridges and melted between by the sun. Here and there evenly scattered over the surface lie rocks of all sizes and shapes, torn, as we shall see, from the pinnacles above. Hurrying over the drifts and through the streams of water partially filling the furrows, I struck out for the nearest peak. At its top a sweeping curve of sharp rock led to a higher one, and this to another. On and up I pressed, my injured back complaining sharply and almost compelling a return. The flora was singularly abundant on these extreme hights, but I could only pause for a few rare species. By mistake I first ascended Mt. McClure nearly to the top, when, by chance, I angled a little to the left, and there, a mile away to the south, across a deeply furrowed ice-field, rose the loftier peak of Lyell. My watch told me it was 1:30 P. M., and I knew I was at least 10 miles from my bivouac. But my resolution was immediately taken. I slid down an incline of splintered rocks to the ice-field, climbed over rib after rib of the hard snow nearly to the base of the shining pinnacles, before I came upon the widest crevasses of this ice-field. [One I discovered too late for my comfort. In my haste I ran up the side of a rib and sprung over to slide swiftly but without injury to the bottom of a crevasse about 12 feet deep and four wide. Here was an adventure! However, I was glad that chance thus gave me an opportunity to inspect the bottom of a glacier, after which with my ever-ready botanical pick I dug holes in the inclined lower side of the crevasse for fingers and toes, and was soon on the way again. As I gazed up the culminating peak, and saw barriers innumerable with beetling crags surmounting almost vertical walls, I became well-nigh discouraged. But around to the south side appeared a heap of talus (broken rocks), and I judged a passage of some kind must be there; so I hastened around to see. There was a passage to be sure, but what a fearful one! A soft stratum of slate rock had crumbled away from between two vertical cleavage planes of granite about six feet apart. At intervals huge blocks of granite were lodged corner-wise in this open cut, while on the bottom piles of debris formed nearly horizontal landings, where temporarily arrested a few rods apart. I at once entered this chasm, for this Appian Way was my only hope to reach the summit. But the situation was frightful, and my nerves which never blanched before, not even when charging a battery of belching cannon, now caused a tingling sensation from head to foot. I think it resulted from the injury to my back. I almost recoiled from passing under boulders that, it seemed, only a touch might dislodge.

Once the landing of debris gave way beneath my feet, and I was precipitated wildly down to the next landing, which, luckily, was strong enough to resist the shock. Having reached the top of my narrow-gauge, I found myself still several hundred feet below the summit. I had read in "Whitney's Guide," that when Clarence King climbed this peak, he was stopped when within about 150 feet of the top by a horizontal knife-edge of 12 feet long. I hoped that my short-cut came out above this barrier, but in a few minutes climb, I came upon the forbidding "knife-edge," with a sheer precipice of 1,000 feet on each side.

Resolutely clambering to it, I clasped my gloved left hand over the sharp edge, and with my pick in my right, dug niches in the side for the edge of my nailed boots, six such cuts enabling me to cross the frightful barrier. Ten minutes afterward I swung my hat triumphantly in the breeze from the highest pinnacle of Lyell, 13,217 feet above the sea!

The views on every side from this peculiarly central station are unexcelled on this coast, but as nearly the same are presented from Dana, which I am next to explore, description is omitted here to give room for promised studies of glaciers and their work, which will be the subject of my next article.

A Snake River Debate.

Saving Fine Gold.

Gold has, for years, been known to exist on the Snake river, but so fine is the gold that it is only very lately that a successful method has been applied there. "This method," says a Park City correspondent of the Salt Lake *Tribune*, "is not generally understood, even by old placer miners, who have mined for coarse gold, unless they have also worked in gold quartz mills. From the knowledge I have of Snake river, I am satisfied there is very little chance of hydraulicking. There is not fall enough, nor is the material of a nature to require that kind of force to tear the cement, clay and other tough material found in gravel diggings. So that I shall describe the process as though the water was to be pumped into the sluices:

"1. You place a line of sluice boxes, long or short, according to the nature of the material that carries the gold; if it is sand without clay or sticky material, a few boxes will be sufficient. In the lower box, before any plates are used, there should be a sheet iron lined box or long-tom, from which all the rock must be forked out, so that nothing but muddy water and fine sand passes down over the plates to be placed below.

"2. Place the boxes which contain the plates as flat as you can, and have the water and sand pass over them without clogging; the slower it passes the more gold will stop. No coarse gravel should be allowed to pass over them or the amalgam will be scratched off. If it is not, it is because it is too hard and not in proper condition to catch fine gold, or coarse either.

"Old mill men will tell you the softer the amalgam can be kept on the plates and not break and pass off, the better its condition to save gold. It is obvious, then, that coarse material should not be allowed to pass over them, and that the line of sluice boxes above should be long enough to wash clean and fork out all but the water and sand.

"3. The boxes containing the plates should be stout, and placed one below the level of the other with a drop of six or nine inches. This keeps the sand stirred up, turns it over and presents new surfaces.

"4. The length necessary to be plated can only be ascertained by actual practice. If the gold is easily amalgamated, a few feet would be sufficient. The only safe rule would be to keep adding plates below as long as any gold stops.

"5. Much has been written about silver plating. While I admit that they are the least trouble, they are *not* absolutely necessary. Take sheet copper, say an eighth of an inch thick, and scour it bright and smooth. This may be done with rotten stone, ashes and soap, or other material that will not scratch or indent the plate. Finish off with dilute acid, either sulphuric or muriatic, by three parts of water to one of acid. This should be kept in a porcelain kettle, to apply to any spot where the amalgam rubs off and the copper shows through. Add to the above solution a little cyanide of potassium.

"6. Now, to amalgamate your plates, get some good silver or gold amalgam, which does not contain much base metal. You can tell this by the feel—if base, it will be greasy and stain the fingers, if pure, it will squeak when pinched, and will not soil the hands. Soften this with quicksilver, and rub once over the plate at first quite softly. When the surface shows like a silver plate, add more dry amalgam and go over again until a coating adheres that can be rubbed off with a piece of belting, either leather or rubber; and, by the way, this is the only scraper that should be used until the plate is thoroughly and permanently amalgamated.

"If the above directions are followed, a plate will be produced that no speck of gold on Snake river can tell from a silver plate, and will not pass over it to meet one. Sheet copper can be found almost any place where quartz mills are operating, and can be prepared by miners themselves. The delay and expense of sending for silver plated ones is beyond the means of most prospectors. A well amalgamated copper is as good and will save as much gold as a silver plate. The difference is, that the amalgam comes off of copper in spots where much splashing or friction exists, as in the inside of batteries, etc., but in sluice boxes, with a uniform body of water passing over them, and close watching to keep them amalgamated, I think they will be found good enough."

In the columns of the same paper, "Snake Bite" thus challenges "'49er." The latter, he says, is correct in stating that silver-plated copper plates are not absolutely necessary in sluice mining. He is "open to correction, however, in regard to the instruction he gives for making the necessary appliances, setting the boxes and preparing the copper plates.

"1. It is not necessary in the new machine, to fork out the coarse rock, as he states, it would cost too much.

"2. He is in error when he directs to 'place the boxes as flat as you can' to catch fine gold. The finer the gold the steeper the boxes should be set, as the sand will pack in a box with little inclination, and the fine gold will not work its way to the bottom.

"3. While I agree with him that silver plating is less trouble, it is not absolutely necessary, but his directions for amalgamating will produce the very results that silver plating is designed to prevent, to wit: the oxidation of the copper and the consequent discoloration of the plates. No acid should be used; and the plates can be amalgamated without it if you know how (there is the rub), and be as efficient as if plated with silver.

"Miners are beginning to realize that placer mining can be improved upon as well as mill processes, and the new mode of working, I have no doubt, will result in the output of millions of dollars in the region of country along and near Snake river.

Gold Sands.

The following paper was read before the California State Geological Society: A short time ago a gentleman having a patent for the use of petroleum as fuel in making iron and for the smelting of lead and other ores, called at the rooms of this society for information as to the situation, extent and richness of the iron mines of this State. Our worthy Secretary, Mr. Heydenfeldt, after having put him in possession of the required information, gave him a letter of introduction to me. At the time he called to deliver it, I was reading Mr. J. H. Godfrey's paper on the geology of Japan, published in our *Quarterly Journal*, August 1st, 1878, wherein he says: "About two-thirds of the whole production of iron in Japan is derived from the treatment of the sand of magnetic iron ore. The principal deposits of this iron sand are found along the eastern and southern shores of the main island (Nippon), and usually they appear to have been derived from the decomposition of the neighboring granitic rocks."

In another place he says: "Sand of magnetic iron ore undoubtedly derived from the adjoining volcanic and metamorphic rocks, is frequently met with along the seashore and largely used for manufacturing an excellent quality of iron, as for instance at Nakayama, Province of Gueshin." Having the facts in my mind, I suggested to Mr. Eames to make a trial of the magnetites, in our gold sands, which are to be found in such quantities on this coast, the condition of such ore being, as I conceived, so well adapted for the flame from petroleum. Mr. Eames, I am pleased to say, is now erecting a trial furnace at old Saucelito, and I feel very sanguine as to the results. I make no doubt but what he will be able to manufacture the shoes, dies, etc., required for our quartz mills direct from the ore. If the ore is obtained from our gold sands two dollars per ton should pay for concentration, leaving the gold for profit. Manufactures of this kind, giving employment to so many, ought to receive every encouragement. The fuel and ore exist in abundance on this coast, and also the best market for the manufactured article, which in reality only requires labor to produce it.

I have had a number of samples of sand sent to me from the beach near the Ocean house. The first I tried yielded at the rate of $5 per ton for gold, and contained about 25% of magnetite, with some chrome. The others gave about 50 cents per ton for gold, and from 15% to 65% of magnetite. The concentration, I imagine, would be a very simple affair, but the ore should be made as clean as possible, and ought to contain at least 90% of magnetite. Two of Bunton's ore dressing frames would, I think, do the work of concentration very well. The prepared canvas of the first frame should revolve more rapidly than when used in dressing lead ore, and have a slight percussion movement added to it, the strength of the blow from which ought to be so arranged that the person attending the frame could vary it to suit the work. The second frame should have the prepared canvas covered at intervals with silvered plates, and be worked slower than the other frame, and so placed that the partially dressed ore from the first could pass over it.

Mr. A. exhibited drawings of two gold-washing machines which were used 200 years ago with direction of how they were worked; also, a diagram and description of Brunton's ore dressing frames, published in the London *Mining Journal*, in 1846, and ore by himself for treating lead and copper slimes, also published in the London *Mining Journal*, 1843, and one cut out of the MINING PRESS of San Francisco last week.

The use of petroleum as a fuel bids fair to revolutionize all our smelting operations, and it will not be long before it will take the place of coal in the treatments of copper, silver, lead, and other ores, even in the calcination and distillation of zinc; but by far the most important will be in iron making, particularly in the puddling furnace. Where a constant and high temperature under perfect control is required, it will take the place of everything else—indeed, the only limit to its use, I think, will be its cost.

MECHANICAL PROGRESS.

Iron in Car Construction.

Much thonght and labor has been expended in the construction of railroad cars, to obviate the necessity of carrying such a large proportion of dead weight, as has hitherto been considered necessary, whether for passengers or freight; any improvement which will bring about a favorable change in the ratio between dead load and carrying capacity must be of proportionate value. Mr. Albert F. Hill, of Cincinnati, recently read a very interesting paper on this subject, at a meeting of the Master Car Builders' Association, from which we extract as follows:

Remembering that the same mechanical principles which govern the design and construction of a bridge hold equally good in the construction of a roof or a warehouse floor, etc., there can be no impropriety in considering a freight car-body as a perambulating bridge, or a bridge on wheels. Conceding this view of the subject to be tenable, it will not be difficult to determine the proper principles which should *govern* and the proper materials which should *enter into* the construction of freight cars.

The tendency to substitute iron for wood in engineering and architectural structures has of late years steadily increased, until at the present time the wooden railroad bridge has become the exception and the iron bridge the rule, and it will not be long before steel will supersede the iron in large spans. In our cities, iron buildings or stone buildings with iron doors supersede every year more and more brick and wood. Durability, strength, lightness and elegance of construction, as well as true economy, are the principal qualities by which metallic structures commend themselves.

Applying this to car construction, I think the point of greater, in fact considerably greater, durability will be readily conceded. Unfortunately, no reliable or rather *positive* information as to the life of freight cars seems obtainable, under our present system of freight service, and the continual interchange of cars over the different lines. Still, barring accidents of course, it will be safe to assume the life of a car-body to vary from eight to ten years at the most. There are some few instances of greater durability on record, but mostly on roads which have but little freight traffic and less interchange over other roads. The life of a metallic car, on the other hand, may safely be estimated at from 35 to 40 years.

In order to illustrate his views, Mr. Hill instituted a minute comparison between the best constructed ordinary wooden-box freight cars, and the iron car which he proposed. He dissected the wooden car piece by piece, giving the weight and strength of each, and then rebuilt the same car with iron wherever that metal could be introduced. We have not the space to go into the particulars of this illustration, and can only give his conclusions, which were summed up as follows:

I have made a rough calculation of the weights in that car, and I get the following results (some of these are accurately calculated and others only approximately, but near enough for all practical purposes): I get two trusses weighing 1,680 lbs.; rolled and wrought iron, 1,760 lbs.; cast iron, 300 lbs.; wood, nearly 4,000 lbs. I think I might be able to do it with considerably less wood yet, but I have assumed the same floor system that is in this car, and that, with the end oak timbers and buffer blocks, and some inside lining, runs up to 4,000 lbs.; and of sheet iron, 2,260 lbs., making a total of 10,000 lbs. Now this car stands thus: Approximate weight of body, 10,000 lbs.—and the weight of the car will fall within that; it can be constructed with less; then for two trucks, 8,700 lbs., making a total of 18,700 lbs. for the whole car ready for use, with a carrying capacity of 20 tons. The wooden car which has served in its general dimensions and general arrangements as a model for this metallic car has a carrying capacity of 12 tons, and a total weight of 22,000 lbs. Granting that this wooden car when new and in good condition, can carry 15 tons, though I think that this is the maximum that ought to be put in that car, we have increased the carrying capacity 25% and reduced the dead weight nearly the same amount.

That a metallic car constructed as this is, will effect such savings as indicated here, is open to the calculation of every one of you. There is no difficulty in calculating these strains and in getting the amounts of metal that are necessary for those strains.

The above-mentioned of gain in weight and capacity, it will be observed, is calculated for a car of the ordinary size of wooden cars; but Mr. Hill proposes to add greatly to the length of the cars when made of iron—or what would he still better, of steel. His ideal metal car would be at least 45 feet long, built upon the principle of the truss bridge. Indeed he calls his car "a bridge on wheels."

Where the real saving in metallic cars will come in will be by lengthening them out, and lengthening them out considerably. With every foot that you add, you will not only increase your carrying capacity, but, if you will go far enough, you will not only increase your carrying capacity for that foot, but you will decrease dead-weight in still greater proportion. This car [the small metal car built of the same dimensions with the wooden box car of which he had been speaking] is altogether too light a car to employ steel in sufficiently large quantities in it; but get a truss 45 feet long and give that car a carrying capacity of at least 40 tons, and you can take advantage, in almost every member of that truss, of the greater tensile and compressive strength of steel.

Testing Boiler Iron.

The following is from a late report of a Government official on the important matter of boiler inspection. It is evidently necessary that a positive and generally accepted rule be established for deciding this important matter. It is believed that the efforts now being made by this office, and supported actively by manufacturers generally, will introduce into the market iron of American manufacture for marine boiler use, equal if not superior to that made in any part of the world, but whatever the quality of the iron the eccentric manner of its wear under steam is not yet explained. Some plates oxidize as soon as used; others of identical texture and position, wear for years without material deterioration, while others again, after wearing for several years without apparent damage, suddenly oxidize and are destroyed in a few months. This last condition was forcibly illustrated by the steamer *Magenta*, which exploded the outer shell of her steam chimney on March 23d, near Sing Sing, on the Hudson. He refers at length to the *Magenta* explosion and says: Such disasters can be avoided by frequent and careful inspection. There are places, however, in all boilers where personal inspection is impossible and where a hydrostatic test must be relied upon. I recommend to all steamboat owners the importance of demanding such tests frequently, especially when, after a season of inactivity, work is resumed; for experience proves that boilers deteriorate more rapidly while idle than when continuously used. He says that in all his efforts to improve the service he has had the cordial support of steam-vessel owners. It is true they complain that some statutes are unjust to them while affording no advantage to the public, and they are naturally opposed to being compelled to purchase worthless patents. It is not appropriate for him to discuss their wrongs, but he hopes justice may be done them, for as a class they are ready to comply with every wholesome provision of the law. Of the total number of vessels inspected, 260 belong to the Pacific coast, with a tonnage of 108,532; 1,820 to the Atlantic coast, with a tonnage of 466,757; 889 to Western rivers, with a tonnage of 186,932; 857 to the northern lakes, with a tonnage of 186,378, and 311 to the Gulf coast, with a tonnage of 68,831.

WHAT IS STEEL?—Difficulties such as these have hitherto prevented the adoption of any of the proposed nomenclatures, says Dr. Siemens, and have decided engineers and manufacturers in the meantime to include, under the general denomination of cast-steel, all compounds consisting chiefly of iron which have been produced through fusion and are malleable. Such a general definition does not exclude from the denomination of steel materials that may not have been produced by fusion, and which may be capable of tempering, such as shear steel, blister steel and puddled steel, nor does it interfere with distinctions between cast-steels produced by different methods, such as pot steel, Bessemer steel, or steel by fusion on the open hearth.

MACHINE FOR MEASURING SUPERFICIAL AREA.—Mr. J. H. Williams exhibited this fall, at the Mechanics' fair, in Boston, a very ingenious machine, which he invented, which is capable of indicating six to eight times per minute the superficial area of surfaces, however irregular, where the surface does not exceed twenty-five square feet. It can compute in less than ten seconds the square contents of a circle without reference to mathematical rules, and it is certain to find practical application in many departments of trade. It will specially be of use to leather dealers and manufacturers, for measuring exactly the superficial area of hides and skins.

THE process of Dr. de Haen for preventing incrustation in steam-boilers, which consists in the treatment of the feed-water with the proper amount of baric chloride and milk of lime, as determined by quantitative analysis, is to be employed for the 310 boilers of Krupp's steel foundry at Essen.

IMPROVEMENT IN SOLDERING IRONS.—A novel soldering iron, the invention of M. Paquelin, was recently described before the Academy of Sciences, Paris. Its distinctive feature is a platinum receptacle, in which heat is instantaneously generated with air and petroleum vapor or air and coal-gas.

CORRECTION.—In our note last week, in regard to the wire traction rope employed by the California Street railroad, the length was given 1,800 instead of 18,000 feet, as it should have been.

SCIENTIFIC PROGRESS.

Experimental Determination of the Velocity of Light.

Albert A. Michelson, of the U. S. Navy, read a paper before the American Association of Science, at its late meeting, on "The Experimental Determination of the Velocity of Light." The paper was pronounced one of the most important read before its appropriate section. Mr. M. said that but three scientists, Foucault, Fizeau, and, more recently, Cornu, have sought to experimentally ascertain the distance of the sun from the earth. Foucault used the method known as that of "Wheatstone's Revolving Mirror," the application of which was first suggested by Arago. Fizeau and Cornu both used another method, known as that of the "toothed-wheel." In Foucault's experiments the distance traversed by the light was 20 meters. The result obtained by him was 185,200 miles per second. Cornu's stations were about 14 miles apart. The result obtained by him was 186,600 miles, which exceeds the former by 1,400 miles. The objection to Foucault's method is that the displacement, which enters directly in formula, is very small, and therefore difficult to measure accurately. The objection to Fizeau's is that the total disappearance of the light was necessarily uncertain.

The object of Mr. Michelson's experiments is to increase the displacement in the first method. This can be done in several ways: (1) By increasing the speed of the mirror; (2) by increasing the distance between the two mirrors; (3) by increasing the radius of measurement, *i. e.*, the distance from the revolving to the scale. In Foucault's experiments the speed of the mirror was 400 turns per second; the radius of measurement was about one meter, and the distance between the mirrors was about 10 meters. The displacement obtained was about 0.8 millimeters. In Mr. Michelson's experiments the speed of the mirror was but 130 turns per second, but the radius of measurement was from 15 to 30 feet, and the distance between the mirrors was about 500 feet. The displacement obtained varied from 0.3 of an inch to 0.63 of an inch, or about 20 times that obtained by Foucault. With a greater distance between the mirrors and a better apparatus he expected to obtain a displacement of two or three inches and to measure it to within one-thousandth part of an inch. Tables of observation of the velocity of light in air were given by Mr. Michelson, the mean result being 185,508 miles per second.

Cast Manganese.

A late number of the *Chemical News* says that M. Jordan has presented to the French Academy a specimen of cast metal, obtained by treatment of the ores of manganese in the blast-furnace. The composition of this metal is:

Manganese	84.96 %
Iron	8.55 %
Carbon	5.70 %
Silicon	0.66 %
Sulphur	0.035%
Phosphorus	0.005%
Total	99.910%

In subsequent operations the percentage of manganese has been carried as high as 87.4%. The specimen laid before the Academy had been preserved for six months without having undergone any sensible alteration. There was noticed a considerable loss of manganese in the furnace, amounting sometimes to as much as 10%, which, with certain other facts, appears to warrant the opinion that this metal is somewhat volatile at elevated temperatures.

VEGETABLE ALBINISM.—At a late meeting of the London Chemical Society, Prof. Church read a paper entitled "A Chemical Study of Vegetable Albinism," in which numerous experiments were described and analyses presented, the conclusion arrived at by the author being that the white leaf is parasitic upon the green. Whilst the author did not give any decided opinion as to the cause of the whiteness, he remarked that white leaves are usually weaker and thinner, and that albino cuttings cannot be "struck." Some attempts have been made to stimulate albino foliage, but without any decisive results.

At the same meeting an interesting paper was read by Dr. Carnelly, on the "Relation between the melting points of the Elements and their co-efficients of expansion." Certain theoretical considerations led the author to the conclusion that the co-efficient of expansion of an element by heat would be the greater the lower its melting point. This conclusion the author has tested in the case of 31 elements, and finds that, with five exceptions, the co-efficient of expansion increases as the melting point diminishes; the five exceptions are, As, Sb, Bi, Te and Sn. A table and a graphic curve accompany the paper, which the author promises to supplement by a communication on a simple relation existing between the heat evolved by a chemical reaction and the melting points of the reacting and resulting bodies.

Barcenite—A New Antimonate.

A heavy, nearly black mineral, which has been discovered at Hitzneo, Mexico, by Senor Barcena, and to which his name has been given, has proved to be an antimonate of hitherto undescribed character, mixed with finely-divided mercuric sulphide and antimonic acid. Heated alone before the outer blowpipe flame, the mineral decrepitates slightly, turns white or nearly so, and becomes rounded (with some difficulty) on the edges, giving off a little white fume; in the reducing flame the fume becomes more abundant from reduction of metallic antimony, followed by volatilization and burning in the outer edge of the flame, which is colored greenish-blue. A fragment heated in a closed glass tube gives off water, metallic mercury, black mercuric sulphide and a very little oxide of antimony; in a tube open at both ends the whole of the mercury is deposited in the metallic state, the sulphur being burned off, and in a good draft of air through the tube more oxide of antimony is carried along and deposited. A well-marked white antimonial sublimate is produced by heating on charcoal, and if sodium carbonate be added the antimony is easily reduced to little metallic beads. The mineral in powder is largely dissolved, in the oxidizing flame by borax or microcosmic salt to a clear, colorless glass, which become turbid in the reducing flame. The mineral, even when finely pulverized, is insoluble in hydrochloric or nitric acid, though this he concentrated and at the boiling temperature. It is very slightly acted on by boiling solution of ammonium sulphide. On boiling with a strong solution of sodium hydrate, filtering, acidulating and passing in hydrosulphuric acid, an orange precipitate is obtained in no great quantity. Hydrogen passed over the powder at a red heat easily reduces metallic antimony, which can then be attacked by acids. The quantitative analysis was made by Mr. J. R. Santos, of Guayaquil, Ecuador. He obtained:

	Atom'c	Ratios.
Sulphur	2.82	.088
Mercury	20.75	.104
Calcium	3.88	.097
Antimony	50.11	.418
Oxygen (by difference)	17.61	1.101
Water { constitutional 3.50 / lost below 130° C. 1.23 }	4.73	
Silica	.10	
	100.00	

DISEASE OF CHESTNUT TREES.—The *Comptes Rendus* of the French Academy of Science contains an interesting note by M. Planchon on the subject of the disease at present prevailing among the chestnuts of the Cevennes, and which is probably identical with that noticed in the Basses-Pyrenees and in upper Italy. The chief symptom visible outwardly is the decay of the extremities of the branches, sometimes one after another, and sometimes all at once, in which latter cases the tree quickly dies, though in others it may last in a more or less diseased state for two or three years. This gradual or sudden death of the branches, M. Planchon found to be consequent on an alteration of the roots. If these be laid bare, parts of the wood and bark of the larger and middle-sized ones are seen to be softened as if by a kind of gangrene, and a fluid exudes from their tissues which, owing to its containing tannin, forms an ink with the iron in the soil, and stains the earth round about for a considerable distance. The roots thus affected, from the smallest radicles to the largest trunks, are characterized by the constant presence of a mycelium or fungus which assumes various forms, but which always appears subsequently on the trunk of the tree in the same form that it was present on the underground portion of it. It generally presents itself in the form of more or less ramified whitish-yellow strings, and is probably closely allied to the *Agaricus melleus*, which plays such havoc with fir trees.

HEAT-CONDUCTING POWER OF ROCKS.—Some time ago Prof. Herschell and M. Lebour made a series of experiments on the heat-conducting power of rocks. Twenty-eight specimens were reduced to uniform circles of five inches diameter and one-half inch thick, but of six specimens that had been tried, slate plates cut parallel to the plane of cleavage transmitted the heat faster than any of the others. Where the flow became uniform the water was raised 1° Fahr. in 32 seconds; with marble, sandstone, granite and serpentine, about 39 seconds were required to raise it by the same amount. The greatest resistance to the passage of heat was offered by two specimens of shale, gray and black, from the coal measures in the neighborhood of Newcastle, which occupied 48 to 50 seconds in raising the water one degree, or half as long again as that taken by the slate.

A QUARTZ THERMOMETER.—Quartz, by its rotary power, M. Jeannet asserts in the *Comptes Rendus*, constitutes a thermometer of extreme sensibility, fulfilling the essential condition of every thermometer, comparability. When once the apparatus is fitted up it is merely needful in order to find a temperature to read off an angle, and refer to a table calculated once for all. It may therefore be hoped that science, and even industry, may find in this new thermometer an instrument comparable to the mercurial thermometer for the simplicity of its use and the certainty of its indications. The author's experiments extend from—20 degrees to plus 840 degrees, or perhaps 1,500 degrees.

Assistant Treasurers of the United States have been instructed to make no distinction between coin and legal tenders after January 1st, 1879.

The loss in wages by the Oldham strike, now terminated, amounts to £60,000, besides the expenditure of Union funds, and a loss to capital by the stoppage, of 4,000,000 spindles.

A further enormous depreciation of Turkish paper money has occurred.

Over 10,000 bales of cotton burned at Charleston, S. C.

Mining Share Market.

There are decided symptoms of recovery in the market, especially in the Comstock shares. The Bodie stocks may remain rather low for some little time to come, particnlarly those fated ones whose mines are in that unfortunate section 16, township 4 north, range 27 east. Taking the market as a whole, it has heen prophesied that the new year's activity will far excell that of the old year; the prophet hasing his plan for the fnture, partly upon honanzas, which have hardly kept the market alive for the last month or more, partly upon the greater depth attained, and more complete developments made in old mines, and partly, which is the most sensihle of all, npon the new discoveries in Arizona and Utah. Meanwhile, instead of prophesying, let us review the solid work of the year. The gross hullion yield from our mines, west of the Missouri river, has heen (as far as Wells-Fargo's books show) $78,276,167, against $95,811,582 in 1877—a falling off of $17,535,415. Dividends paid at San Francisco during the past year have amounted to $26,649,300, of this, two-thirds was paid hy mining companies, amounting to $18,234,700. It is the mines of California, Nevada, Utah and Arizona that pay their dividends at San Francisco. These four have produced, according to the same authority, $62,455,004. Taking from this the dividends, we have $44,220,304, or ahout five-eighths of the products of the mines returned into them. This, of course, takes no cognizance of assessments nor of capital already invested.

The Betchel and Sitting Bnll have consolidated, the company taking the name of the former.

The distress among the poor in England seems to have reached its crisis.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

ALPINE.

THE MINES.—Bodie *Chronicle*, Dec. 21: Lewis Chalmers, Manager of tha new London company—the Isabella — has arrived at Silver Moantain and is making preparations to commence work on the tunnel, the location of which is being surveyed by U. S. Depnty Surveyor L. L. Hawkins. Heavy machiuery is on the way to drive the tunnel at the rate of 200 feet per month. H. C. Ginn has contracted to build a bridge across Silver creek, near the site of the praposed tunnel. Arrangements for resuming work aa the Tarshish are progressing favorably. Coasiderable wood is being cut in the vicinity of Mouitor in anticipatiou of an early resumption of work ou the Advance and Tarshish. It is reported that three shifts will soon be put to work in the Jones drift on the Advaace. It is thought by exports who have examined the mino that the Jones drift will soon tap an immensa ore deposit.

AMADOR.

VOLCANO ITEMS.—Jackson *Ledger*, Dec. 28: Stewart's mill has got fairly started on Downs' rock again. The mill is now in fine condition for work. A crushing of quartz from Jones and Robiuson's claim, at the Stewart mill, yields an avcrage of $11 per ton. Moyle & Co's claim in Volcano basin is all ready for the commencement of operations. The lack of water is the only thing that prevents active miniug. The works have been fixed up at a vast outlay to raise the pay dirt to a hight of 60 feet, thereby ensuring a sufficieucy of fall and pumping facilities. All the workmeu have been discharged with the exception of two. The Rising Sun mine is at a standstill. The owners went to considerahlo expense in fixing up the mine and erectiag a mill, only to meet with disappointment. At the Tellurium, sinking operatious are heiug pushed ahead, through rock of the hardest character.

MOORE MINE.—Jackson *Dispatch*, Dec. 18: The ditch will he completed this week, and iron pipe is being hauled to those places where pipiag will he necessary. It will require but little time and labor now to render the ditch ready for the reception of water.

BUTTE.

A GOOD PROSPECT.—Chico *Record*, Dec. 28: A few days ago, John Allen, of the Jnnction, went np to Butte creek prospecting, and at various points on the creek, tested the richness of the ground hy panning. At one place he secured about five dollars from four pans of dirt, ane piece alone weighing almost four dollars. John has a strong idea of tarning honest miner.

GONE TO MINING.—Oroville *Mercury*, Dec. 27: A. E. Brittin, recently in the furniture husiness in Biggs, has forsaken that pursuit, and in company with Mr. H. Carrington, of the same place, embarked in mining near Powelton. Both gentlemen are experienced miners and prospectors, and will, we helieve, do well.

CONTRA COSTA.

JUDSONVILLE.—Antioch *Ledger*, Dec. 28: This town is situated about five miles south of Antioch, and about three and one-half miles from Somersville. Coal was discovered near this place as early as the year 1852, hut none of the most valuahle mines were discovered until 1868 to 1870. The Teutonia mine was located in the year 1868. This is the pioneer coal district of the Golden State. The Teutonia faces the location of the Judsonville Coal M. Co. The present owners hegan operations here ahout three years ago. The depth of the slope is now 900 feet. The company have expended a groat deal in machinery and in huilding a narrow-gauge railroad from Antioch to the mine. The quality of coal is something similar to the Somersville coal. The coal is shipped to Sacramento and Stockton, and considerahle quantity of it is consumed for domestic purposes in San Francisco. The company are shipping some 2,000 tons per month.

INYO.

A PROCESS WANTED.—*Independent*, Dec. 21: Some 35 or 40 miners and prospectors are now engaged on the small rich gold mines of Alahama district, to the northwest of Lone Pine. Two reduction works are in operation, the yield of fine gold proving the work very profitahle. At present, however, the Orion or Schnlte mine, one of the largest and first worked, is shut down, owing to the practical impossihility, so far, of separating the fine gold from the iron sulphurets, which seem to he a peculiarity of the mine. Experiments are going on to determine some method of handling them, and it is prohahle that a small roasting furnace will he put at work. Were the Beveridge and the Alabama gold fields anywhere near such a rush as Bodie, there would he thousands of men at work in them the coming summer.

ITEMS.—The Brown Monster ore hodies are developing well. The mill was not started on time on account of tho ice in the mill-race. The expenditures of the Rex Montis up to December 12th, amounted to $161,869.18, $68,-912.79 of which was paid from hullion. The assets, exclusive of the valuation of the mines, foot-up $75,571.20, giving a surplus over liahilities of $48,572.92. The long tunnel and the shaft of the Modoc, are progressing favorably. The Emigrant Campany, Lee district, ships bullion every week. The Custer, under the management of J. S. Gormau, has good prospects.

PLACER.

IOWA HILL.—Auburn *Herald*, Dec 28: The Morning Star company aro preparing for a blast of 225 kegs af powder. They are laying down railroad iron riffles in their tail sluices. Mr. W. W. Anderson, af Gold Run, has been elected superintendeut of the Orion claim, Iowa Hill. This coapany will hegin to wash about the middle of January.

CANADA HILL.—Canada Hill is 25 miles up the divide from Iowa Hill. It is on the North Fork of the Middlo Fork of the American. There are now about 20 miaers residiag at that camp. Thero are three tuunel claims, and one hydraulic claim, with a water ditch of four miles in length. One of the miners, now ou a trip helow, says that the camp is iu a prosperous condition. The same may also be said of the miniug camp at Last Chauce.

PLUMAS.

EUREKA MILL.—Quincy *National*, Dec. 21: The new quartz mill which the Plumas Eureka company have heen building, started up the other day, and runs satisfactorily. It runs by water power and adds 40 stamps to the large uumber already at work. Tho mill is probably one of the most costly in the State, having all the modern improvements, and has been fitted up regardless of expense. Our old and valued correspondeut, "Alioth," promised us a full description of tho new mill when it was completed, aud we shall look for his letter in a short time.

SANTA CRUZ.

PROSPECTS FOR COAL.—San Jose *Mercury*, Dec. 27: Ever since the survey of the South Pacific Coast railroad and the commencement of the work of piercing the mountaias with a number of tunaels, it has been helieved that valuahle discoveries would he made and mineral secrets long hidden heneath the crags of the Santa Cruz mountains would he brought to light. Espocially has it been a matter of interest as determiniag to almost a certainty whether or not there are in these hills any considerable heds of coal. Some time ago we puhlished a statcaent that the tunnel was then progressing through a species of rock greatly resembling coal, which was in an iaferior degree combustible, and which gave out gases very similar to coal gas. While these were not to he taken as evidences of the existence of coal in these hills, it did prove a condition of things at one time which rendered it very prohahle that the conditions necessary to the production of coal here had also heen perfect. This prohability has now become a certainty, as the workmen in tunuel No. 3, working at the south end, have discovered and penetrated a vein of excellent bituminous coal about eighteen inches in width, and intersecting the tunnel from east to west.

SIERRA.

MACHINERY FOR PLUM VALLEY.—Downieville *Messenger*, Dea. 28: Twenty tons of machinery for Culver & Co.'s mine at Plum valley, ahove San Juan, has heen received here, says the Nevada *Transcript*. The lot includes hoiler, engine, quartz crusher, etc. The mine is said ta have good prospects, and will he worked quite extensively as soon as the mill is completed.

TRINITY.

TAYLOR FLAT.—Weaverville *Journal*, Dec. 28: Mr. Walker, another San Francisco miniag expert who visited Taylor Flat this week, expresses himself as highly pleased with the prospects of that section. He thinks it one of the richest gravel deposits in the State.

CINNABAR DISTRICT.—Mr. J. F. Dolliffe, from the ahove district, called on us this week, and from him we learn that the Altoona company has lately struck a new vein of ore of exceeding richness; also that a new superintendent has heen placed in charge of the mine. Mr. Dolliffe further informed us that he had found some very encouraging prospects in his own mine recently.

TUOLUMNE.

CHAPMAN.—Sonora *Independent*, Dec. 28: The Chapman mine, near the Confidence mine, promises to he good property. The vciu is 33 inches wide and shows free gold and large quantities of rich sulphurets. Two or three shafts bave heen sunk along the lode, as far as water would permit, and for lack of pumping apparatus work has been suspended for a time. Here is a good chance for enterprising capitalists.

CONFIDENCE.—The miners in the Confidence are gaining on the water, and also running a drift in No. 5 level and raising good ore.

NEVADA.

Our usual summary of Washoe mines did uot oome to hand on time. The following regarding Nevada mines is taken from letters:

SAVAGE.—Letter of 31st says: There is nothing new in the mine to report. Working along as usual in crosscnt and drift. Everything working well.

SILVER HILL.—Letter of the 28th says: We have run the St. Louis drift 34 feet siuce last report, and the 1100 level crosscut 10 feet. Our new pump is running first-rate, also our new boh.

CHOLLAR.—Letter of the 28th says: At the Chollar-Norcross-Savage shaft during the past week we have been working on pumps which are nearly finished. We have eased and repaired 45 feet of the shaft.

GRAND PRIZE.—Letter af the 30th says: Ledge in crosscat on 500 level looks very well. The ore is rich; will mill over $200 per ton. Water coatinues very strong in face of crosscut aud progress will be slow for a few days until the ledge drains out.

MANHATTAN.—Letter of the 27th says: During the past week the mill redneed 144 tons and 290 pounds of ore of the value of $28,944.-54. Of this amount, $9,301.03 was from custom ores; $5,916.63 from tnihute mines; and $13,726.83 from the Frost and Curtis shafts.

HALE & NORCROSS.—Letter of the 30th says: Our east drift on tho 2000 level has been advanced 81 feet siace last report aad is uow 811 feet. No material chauge in the character of the ground, 16 sets of timbers have been set up. The water stands to-day 54 feet below tho 2000 level.

ARGENTA.—Letter of tho 27th says: East winze No. 1, 200 level, is down 28 feet. Sample of ore from bottom to-day assayed $1,700 per ton. The face of east drift, 200 level, looks as well as usual. East drift, 200 level, is lookiug better thau at last roport. Stopes are all looking well.

RAYMOND & ELY.—Letter af the 23d says: During the week nothiag new has transpired. Crosscut on 1400 level measured 66 feet yesterday. The last 10 feet in quartz heavily charged with pyrites and quite hard. Have started drifts east and west ia hangiag wall and will soon make two other crosscuts. Tenth level about the same as last report; looking a little better in the east end aad not quite as well in the west, where the formation seems more broken than heretofore. Old levels are turning out a little good ore all the time. The mill has commeuced workiag low-grade are and tailiags.

UTAH.—Letter of the 28th says: Our main incline bas been sunk and timbered 16 feet the past week and is now 180 feet below the 1350 level. The bottom is in good working rock; the flow af water continues ahout the same. We are making some repairs in the incline. Our improvements on the surface are progressiag rapidly.

HAMBURG.—Letter of the 29th says: There is no special change to note in appearance of ore in north drift 40 feet below 250 level. South drift, same level, shows a material improvement, the vein of oro having widened and coutinues to be of extra good quality. North drift 80 feet below 250 level was continued 22 feet, making a total from winze of 84 feet; near the end of this drift we have started an npraise on the vein to connect with the ore in bottom of north drift 40 feet ahove. West crosscut from end of south drift, 600 level was advanced 20 feet, face still in favorahle vein matter. We have shipped to the furnace during the week 75 tons of first-class ore.

ARIZONA.

We condense the following from the Prescott *Miner*, of Dec. 13:

OCCIDENTAL.—Marshal Duke, interested in this gold mine on Lynx creek, thinks favorably af the prospect. The mill, now in order, will soon start up on first-class ore. Development is carried on hy ten men.

MCCRACKIN.—In the Bateman tunnel, 900 feet below the surface, a very rich strike has been made. Twenty men are developing the mine.

A NEW FIND IN THE JUNIPER RANGE.—Messrs. Cooney, Burns and Waters, have located some very rich silver ledges near the headwaters of Sycamore creek, a trihutary of the Santa Maria. The discoveries are in a helt of slatc. Assays go up into the thousands.

COLORADO.

GENERAL MINING NEWS.—Boulder *News and Courier*, Dec 20: The Terrihle mine at Georgetown is heing again profitahly worked. It is estimated that 100 feet square of the Little Pittshurg deposit is worth, in round numhers, $1,000,000. The Long and Derry mine at Leadville has heen honded for 60 days hy Mr. Teats of Gilpin county, in hehalf of Senator Teller, for $260,000. Some ore from a new discovery near Twin lake, in Lake county, assays 22,000 ounces to the ton, of horn silver. The ore resembles hlack lava, and appears in large quantities. Ten-mile district, near Leadville, will be a famous locality hefore another winter rolls around. Recent assays have returned 1,800 ounces of silver per ton from heavy deposits of mineral. In Summit district, a rich strike has heen made in the Little Annie mine, showing much free gold. This class of ore is sacked and sent to New York. It fairly bristles with gold. The mine has kept its 10-stamp mill husy the entire season. We learn from the *Chieftain* that a new excitement has arisen in Puehlo over the discovery of a rich silver mine in Dry creek, ahout three miles north of town. Specimens of the mineral were assayed at the lixiviation works, and gave large returns. The Little Chief mining property, at Leadville, was sold Tuesday to Chicago parties for $360,000. A good strike has lately heeu made in the Dunkirk lode, helonging to the Herman mining company, of New York.

IDAHO.

SNAKE RIVER.—Boise *Statesman*, Dec. 21: Mr. Miles Burston who resides on tho Snake river hottom a few miles helow Salmon falls, was in town yesterday, and from him we learn that there are several companies uow organized and at work on the bars of that section of the river. Tho numerons large springs which gush out from the banks of the river for several miles on the north side afford an ahundant supply of water, which will now be utilized in working the hars, where prospects as good as those af the great Bonanza har have heen fouud. Mr. Burston says that parties have been prospecting the river as far dawn as the mouth of the Bruneau, aad have found gold in quantities that will pay well hy the new process, which they are alsa preparing to introduce.

RUTH DISTRICT.—Boise *Statesman*, Dec. 24: Mr. John Atwell came iu on Saturday from Ruth district, Weiser miaes. He has been engaged in quartz mining in this district for four years past. Work has gone on very slow and only a few meu have been eagaged in the mines—only five men on them now. Mr. James Ruth will have his quartz mill in operation early in the spring. The battery is put up in its place, and the rest of the inside work will be put in this wiuter. The Indian troubles put them back a good deal last summer and summer before, but a few meu have beeu there all the time, and they have several well-defined leads opened, and they are very sanguine that another year will put some of these mines into a prosper aus and paying coudition.

MONTANA.

RICH STRIKE IN THE LEXINGTON.—Helena *Independent*, Dec. 19: New and very rich bodies of ore have recently heen developed in the Lexington miae ou Teu Mile. At the present time the shaft is 160 feet deep and the lode is four feet iu width. There are streaks of ore ruaniug through the lode that assay $5,000 to $20,000 per ton. The mino has always paid expenses, but nover before had such a bonaaza.

ITEMS.—The Bluehird hoisting works have heen destroyed hy fire. Christ, King, Fred Muller & Co., have good pay in Central district. The Benson honanza, New York gulch, will no doubt pay well when experienced meu take hold of it. The suit, at Helena, of King vs. the Natioaal Miniug Co. for $500,000 damages by trespass, has heen decided for the defendaut. Eleven tons of Bercaw ore yielded hy arastra $226. It is reported that there is euough ore in sight at the Penohscot to keep 100 stamps running for a year. The Hope mining company at Philipshurg, are still taking out ore. The Northwestern company have laid in immense supplies of wood and salt. From three to four feet of the lode tapped hy Murray & Durfee iu the Sharktown tunnel samples 130 to 200 ounces per ton. The whole lode, over nine feet wide, carries paying quantities of silver.

NEW MEXICO.

GEORGETOWN AND SILVER CITY.—Quartz writes to the Salt River *Herald* from Georgetown, under date of Dec. 11th: Most of the miners are doing well. Kennedy & Harper are constantly taking out ore. Deller & Webster have taken out some 25 or 30 tons of $200 ore duriag the last two or three months. John McGregor has a lease on a large streak of rich ore. Lemon & Kitt, lessees of the McNulty, have struck a rich streak. The Naiad Queen, Meredith & Ailment, keep six hammers husy on are which yields from 100 to 2,000 ounces per ton. The Commercial and Satisfaction are turning out a great deal of ore. The mines ahout Silver City show equally hopeful signs. In the Legal Tender and the New Issue it is estimated that there are at least 2,000 tons of ore in sight, which may pay from 20 to 500 ounces per ton. Their ores principally cousist of gray carhonates, sulphurets and chlorides and some heautiful specimens of horn silver may ho seen at all depths, as far as they have been worked. In fact oue can scarcely hreak open a piece of quartz that does not show more or less horn silver.

OREGON.

MINING ITEMS.—Jacksonville *Sentinel*, Dec. 25: T. L. Beck, of Willow Springs, last week picked up a gold nugget weighing $18.75 while cleaning up the hedrock on his claim. McKnight & Goldworthy of Foot's creek are now ready to hegin hydraulicking. Byhee, Hawkette & Co., near mouth of Slate creek, have suspended on account of the freezeup. All the hydraulic miners in this county are ready to commence work as soon as they have water. It is now feared that the season will be a dry one, as the winter rains during a wet season generally hegin ahout the middle of Decemher. Last winter, however, very little rain fell before the middle of January, aud still the miners had a long and prosperous run. It is hoped that it will he the same this year.

UTAH.

PARK CITY.—Salt Lake *Tribune*, Dec. 24: McCormick & Co. yesterday received 22 hars of hullion from the Marsac mill in Park City. It is hase, hut runs high in silver, heing ahout 260 fine. This makes the second shipment, the first having heen received on the 17th inst. in 12 hars. That, however, went low in silver. Mr. Ferry, who has the running of the mill, is adopting means to increase the grade of hullion, and save all there is in the tailings at the old Marsac, from which these hars are heing made. Weekly shipments may he expected now while the tailings last.

ORE FROM NEVADA.—Ores from Nevada still come to the Salt Lake market to he disposed of. The last lot came from the Jersey and other mines at Battle Mountain, and was consigned to McCormick & Co., by J. A. Blossom. This ore consisted of three carloads in seven lots of various grades, ranging from 50% to 60% in lead, and from 50 to 150 ounces in silver. Lead ore is just what our smelters need at the present time, and they must have it in order to run.

Mines and Works of Almaden.—No. 16.

Translated for the PRESS from "ANNALES DES MINES."]

Is the condsnsation effected in a snfficient mannsr either in the aludels or in the condensers? If it is hadly accomplished, we should assnredly find mercurial vapors in the gas which escapes hy the extreme chimneys.

M. Lncas de Aldana, to-day Inspector-General of Mines, made, in 1851, a series of experiments upon this snhject; he looked for the mercurial vapors hy placing a leaf of gold (*une feuille d'or*) at ths upper part of ths chimneys. Let us see the acconnt rendered of his experiments (*Revisito minera* t. II., p. 378).

The leaf of gold placed during 12 hours, at the end of the second day of work, npon the extreme chimney of a Bnstamente furnace, had not presented after thess 12 hours anything but a deposit of small drops of water condensed.

After 32 hours of the period of roasting, and 24 of cooling, the gold plate presented a white spot in the center.

After 16 hours of the period of cooling, nothing.

After 24 hours of the period of roasting over the worst of ths furnaces, the spots were a little increased.

After 25 hours, another time, very slight traces.

After 94 hours, they were sensihly amalgamated.

What do these results prove? That there is an amalgamation of the sheet of gold, hy consequence of a loss of mercury, it is true. But not that this loss is elevated. If the loss was 30% there wonld escape hy the two chimneys ahout 350 kilograms of mercury; let us even reduce this figure hy half, admitting that one-half escapes by the cracks, there would still he 87.5 kilograms which would escape hy each of the chimneys during the two periods of firing and of roasting; the amount of amalgamation ssems very small for a plate of gold one decimeter square, over which had passed 87.5 kilograms of mercurial vapor.

These experiments have also proved that the amalgamation seems more difficult in the presence of the vapor of water.

All these contrary considerations would leave us in complets indecision, without the exact experiments to which we have already alluded. We think advisahle, in order to show under what exact conditions these experiments have heen made, to recount hriefly their history. A French engineer, M. Emile Pellet, had presented to the Conncil of Mines (*Junta de minas*), in 1867, the plan of a new furnace for the distillation of the ores of msrcury. The council gave, April 10th, 1867, a report favoring a trial of Pellet's system; the royal order was given June 5th of the same year. The Pellet furnace was hnilt in 1868 and the experiments were hegun in 1869

Let us see the principles of the new method: 1st. Calcination is still adopted; the fuel is coke mixed in thin alternating layers with the ore. 2d. The condensation is accomplished in five chambers of which the last four are divided into two compartments hy a median wall pierced with holes. In these chamhers falls a continuous rain of fresh water. The hottom is covered by a hed of water which ordinarily isolates each chamber from the preceding; the vapors can not pass from the one to the other, except when the bed of water is agitated in such a manner as to disclose the opening. This agitation is produced by the action of a ventilator, which draws the gas and the vapors.

The consumption of water, considerable for an establishment which has at its disposition only that which is extracted from the mines, the necessity of men constantly occupied with the charging and discharging, the necessity of a motor for the ventilator, the need of watching the level of water in the chambers, the impossihility of remedying serious accidents without first cooling off the fire, and, finally, the difficulty of treating the fine ore, were certainly grave inconveniences of the new system; they might assuredly he neglected without hesitation, if the furnace had heen ahle to realize the hopes of its inventor, viz., ahsolute, or at least nearly ahsolute, snppression of the losses of mercury, economy in the costs of treatment, suppression of the mercurial vapors, so injurious to the health of the workmen.

In case of success, M. Pellet required that they should give him, as a reward, the henefits resulting from the application of his system dnring one year. These henefits were estimated to he 3,730,000 francs. The assays were hegun April 4th, 1869, under the direction of M. Monasterio, Inspector-General of Mines, and Director of the School of Mines at Madrid.

M. Pellet first made a preliminary assay of 55 tons of ore; 54,952 kilograms of ore, containing 4,501.523 kilograms of mercury, gave:

	Kilograms.
By direct distillation	2,399.10
Batido de cabezas	508.20
90% of mercury of the residues	348.54
Total	3,255.84

Loss, 1,245.677 kilograms, which is 2,266% of ore treated, or 27.672% of mercury contained. They proceeded theu to a comparative test hetween the Pellet furnace and the Idria furnace. The results of this trial are of great interest, not so much for the Pellet furnace, as that is no longer a question to-day, as for the Idria furnace, which is still in use. In order to give to M. Pellet all the guaranties of equity and impartiality that he could desire, the following arrangements were exactly observed:

The ores divided into 10 classes remained exposed to the air at the disposition of M. Pellet for all ths observations which he wished to make during the month of April. M. Pellet dcclared himself entirely satisfied with the classification.

The two furnaces to he compared were each separated by a wall in such a manner as to permit an exact control of the materials. Three watchmen were detailed hy day and three hy night. The charges were weighed exactly, and they wers made identical for each furnace, hoth as to weight and as to contents. Assays were carefully taken from each weighing, and were made hoth hy the engineers aud hy M. Pellet. All the products were accurately weighed. All other work in the neighhorhood of the two furnaces was prohihited.

M. Pellet himself recognized the high sentiments of justice which inspired M. Monasterio, the character of which was a guaranty of the most perfect impartiality of the experiments.

[To be Continued.]

A NEW INDICATOR.—The Gold Hill *News* thus describes a valuahle invention of Hans Behr, a machinist at the Foulton foundry, Gold Hill: "It is an indicator by which the engineer is to determine the exact location of the cage when moviug up and down the shaft, and thus enable the prevention of many of the accidents that still occur from time to time, with the best patented indicators now in use. Behr's indicator consists of a simple, upright spiral screw, haviug a direct positive connection and action with the hoisting engine. To this screw is attached a hand or indicator which moves up or down as the cage is hoisted or lowered in the shaft, marking with the utmost precision and unerring certainty on a dial plate representing the shaft aud its stations, no matter how many in number, the exact position of the cage. The attachment is so direct, simple and positive, that if the engineer pays attention to the indicator it seems impossible for an accident to occur. This indicator has heen chosen for the works of the North Con. Virginia shaft, an argument much in favor of the invention."

IT is calculated that £2,000,000 a year of property is destroyed by the London smoke.

Harlan's Buzzard.

Our engraving shows Harlan's huzzard which was added to the fauna of ths United States hy Mr. Audubon about the year 1830, and by him called after Dr. Richard Harlan, of Philadelphia. He speaks of two specimens only, which were captured in Louisiana. They had hred in the neighhorhood of the plaes where fonnd for two seasons, but their nests were not seen. Their young are said to appsar of a leaden-gray color at a distance, but to hecome as dark as the adult birds at the approach of winter. These hirds were successively seen perched on the top of a high tree, standing in an erect attitude, and appeared so like the hlack hawk (*Falco niger*) of Wilson, as to be at first taken for it. They were hard to approach, and when severely wounded and captured they proved fierce, courageous and intractahle, and died refusing food. They were considerahly smaller than the red-tailed hawk, to which they are allied, but superior in daring; their flight is rapid, protracted, and so powerful as to enable them to seize their prey with apparent ease, or to effect their escape from the red-tailed hawk, which pursues them on all occasions. They have not heen observed to fall on hares or squirrels, hut at all times evince great fondness for common poultry, partridges, and the smaller species of wild ducks.

HARLAN'S BUZZARD.

COAGULATED PETROLEUM.—If powdered soapwort (root of *Saponaria officinalis*, L.), previously wetted with water, he added to petroleum, no matter how light its density, the two snhstances form a thick mucilage; so that the vessel contaiuing the mixturo may he inverted without any of it flowing out. On adding a few drops of carholic acid and stirring, the mncilage hecomes clear in a few minutes.

MR. GEORGE WYLD, M. D., says: "Although I have always held that electricity, sooner or later was destined to become the light of the future, still my faith in gas is so strong, that I have doubled my stake in gas shares since the scare hegan. Coal gas is destined to hecomo the cooking and heating power of the future."

LINEN and woolen fahrics aro entirely incombustihle if impregnated with a solution containing five per cent. of alum and five per cent. of phosphate of ammonia. They lose this quality hy washing.

THE ENGINEER.

The Effect of Brakes On Railway Trains.

At a recent meeting of the Institution of Mechanical Engineers, at Manchester, England, "The Effect of Brakes on Railway Trains" was the subject of a paper hy Capt. Douglas Galton, C. B., in continnation of a paper read hy him at the Paris meeting of ths institution. He described minutely the results ohtained hy experiments on the London, Brighton and South Coast and Northeastern railways. Recapitnlatiug what appeared from these experiments to be the essential conditions of a good brake, he said the pressure with which the hrake-hlocks were applied to the wheels should he as high as possihle, short of the point which would cause the wheels to he skidded and slide on the rails. In practice, and as a question of safety, it was of the greatest importance that, in the case of a train traveling at a high rate of speed, that speed should he reduced as rapidly as possihle on the first application ot the hrakes. For instance, a hrake which reduced the speed from 60 miles an hour to 20 miles an hour, in say six seconds, had a great advantage as regarded safety over a hrake which would only reduce the speed from 60 to 40 miles an hour in the same time. The maximum pressure should he applied to the wheels as rapidly as possible, and uniformly in all parts of the train. The skidding of the wheel, so that it slid on the rail, was altogether a mistake, so far as rapid stopping was concerned; in addition to this it must clearly cause a deteriorating effect in tending to force forward the rails and sleepers; whereas, so long as the wheels continue to rotate, no such effect would be produced. Railway companies, in considering what form of hrake was hest suited for traffic, must, whilst they gave full weight to the mechanical conditious discussed in this paper, also ascertain the durahility and facilities for maintenance and repair presented hy the varions systems. It was further clear, from the prseut series of extents, that the universal application of continuous hrakes would raise many questions as to the strength of the rolling stock now in use, much of which was constructed originally to meet other conditions of traffic.

Improvements on the Kanawha.

The Government improvements of the navigatiou on the Kanawha river, hy dams and locks, now under way, will tend to develop the resources of this most wonderful region. The *American Manufacturer* says: Ten locks and dams will furnish slack-water navigation from tho Ohio river to Cannelton, a distance of 85 miles, the cost of which will he ahout $250,000 for each dam with lock. Of these ten, there will he three ahove and seven hclow Charleston. These locks and dams are heing constructed of hewn stone, and in the most workmanlike manner. In niue of the dams, however, there is to he an "open pass," 250 feet in length. In this "opeu pass" thers is to he a wooden and iron structure, so arranged that it can he elevated in low water, and therehy furnish seveu feet of water iu the shallowest places in the river, and can be lowered during high water, and therehy furuish free and unobstructed navigation during the rises in the river. Hence these dams are called "uiovahle dams." The first nine dams from the Ohio river are to he movahle dams, which will furnish seven feet of water from Paint creek to the Ohio river during low water, and an open river during high water. The locations aud lifts of the dams will he as follows: At or near the mouth of the Kanawha, eight feet lift; at or near Dehby's Ripple, seven feet lift; at or near Gillespie's Ripple, six feet lift; at or near Red House Shoals, six and one half feet lift; at or near Johnson's Shoals, seveu feet lift; at or near Newcomer's Shoals, six and one half feet lift; at or near Island Shoals, seven feet lift; at Brownstown, seveu feet lift; at Cabin creek, seven feet lift; at or near Paint creek, fifteen feet lift; total "lifts," 77 feet, in a distanco of 85 miles.

Improvement in Our Ship-Building Industry.

So much is said about the impossihility of a revival of the ship-huilding industry in this country under the present tariff, that we are glad to pick up every item hearing on the subject. The following statistics will he interesting in this connection:

During the fiscal year ending June 30th, 1878, 32 irou vessels were huilt, with a tonnage of 25,960.29 tons. This record is second to the hest record the country has yet made, which was in 1874, when the tonnage aggregated 33,097 tons. The next hest record in tonnage was in 1873, when it amounted to 26,548 tons. The numher of iron vessels huilt during the past year was greater than in any other year, the ycar which most favorahly compares with it heing 1873, when 26 were huilt. Of the vessels huilt during the past year, 9 were ocean propellers, varying in tonnage from 1,156 tons to 3,548 tons; 1 was a lake propeller of 306 tons; 1 was a stern-wheel river steamer of 1,028 tons; 7 were side-wheel river steamers, ranging from 128 to 1,285 tons; 13 were steam tugs, the largest of which measured 180 tons; and the remaining vessel was a yacht.

The numher of vessels and the tonnage will, this year, probahly exceed that of any previous

year in the history nf the cnuntry. One nf ths latest launches was the fine steamer *St. Johns*, for ocean and river travel, from ths yard nf the Harlan & Hollingsworth Company, at Wilmington, Del. The *St. Johns* is for tbe Charleston, Savannah & Florida Line, and her measurement is as follows: Length, 260; beam, 38 feet; beam over all, 64 feet. Her cylinder is 66 incbes in diameter, witb 12 feet length of stroke.

At the yard of John Roach, Chester Pa., the double tnrrcted monitor *Miantonmah*, Government vessel, is in hand, receiving her machinery and finishing touches. Two other vessels are on the stocks, nnd a large number of men havs recently been added to the working forcs in the yard, giving it a more lively aspect than it has worn for some time.

Bridging the Bosphorus.—Capt. James B. Eads, the well-known engineer of tho iron bridgs at St. Lonis, who has long been connected with the jetties at the delta of the Mississippi river, bas recently prepared plans for bridging ths Bospborus, thns conncctiug Pera with the Asiatic shore. Capt. Eads was assisted in his calculations and surveys by A. O. Lambert, a civil engineer. The bridge will be 6,000 feet long and 600 feet wide. It will have fifteen spans, and will bs almost entirely built of iron. Ths higbt of the roadway above the surfaco of ths water will be 120 fset, 60 fest less than the elevation of the Brooklyn bridge. Tbe centor arch will be a apan of 750 feet, one of tbe longest spans ever contemplatod. The central piers or main portion of the strnctnre will he 50 feet thick, built of solid granite blocka fastened together with iron braces. The main tiers are 270 feet high from foundation to anmmit. The cost of the entire atructure is estimated at between $18,000,000 and $25,000,000, and six years nre given as the time to complete it. Excellent granite is near at hand, and as the iron work will probahly be done in France and Belginm, there will be no delay. It is also thought that cheap labor can be employed. The increase in the value of property that will necessarily follow the completiou of the work, it is believed, will amply repay the coat of the project. The construction of the hridgo will doubtless do much towards the completion of the Euphrates Valley railroad, making it the preferred route to India.

The Gibraltar Tunnel.—The proposed tunnel between Spain and Africa ia still hcfore the public. This tunnel, according to the plan at present contemplated, is to extend from withiu a short distance of Algeciras, on the Spanish side, to between Tangier and Ceuta on the African side. The length of the submarine tunnel will be nine miles, with an inclination of nne foot per hundred, and the approaches will have an extent of six or seven miles. The greatest depth of the sea is 3,000 feet; and, as it is intended to have a thickness of some 300 feet of rock left hetween the roof of the tunnel and the sea bottom, the greatest depth of the tunnel will thus he 3,300 feet below the level of the sea.—*Am. Architect.*

The St. Gothard Tunnel.—The popular vote on the Gothard juestion, which will probably decide the fate of the enterprise, is fixed for the second week in January. Meanwhile the Federal Council has passed the engineers' estimates for the seventh year of construction. Twelve million three hundred thousand francs have to be spent on the works during the period in question, and it is calculated that by next October the tumel will have been bored to a length of 11,000 yards.

Engineering.—We notice that Col. J. D. Schuyler has been called from his chair as local editor of the Stockton *Independent*, to take a position on the staff of State Engineer Hall. Col. Schuyler is well fitted for this branch of the State's work, both hy talent and education, and we have high trust in his record in his new field. He has an earnest zeal for developing the resources of theState, and we doubt not this will he the moving impulse in the important task which he assumes.

Cost of Artesian Wells.

The *Bulletin* extracts the following from the "Prospectus of the Kern Valley Colony:"

Of iron pipe, double, 7 inches diameter, various depths:

First 50 feet boring, at 50 cents per foot	$25.00
50 feet pipe, at $1.00 per foot	50.00
A 50-feet wel costs	$75.00
Second 50 feet boring, at 50 cents per foot	25.00
50 feet pipe, at $1.00	50.00
A 100-feet well costs	$150.00
Third 50 feet boring, at $1.00 per foot	50.00
50 feet pipe at $1.00	50.00
A 150-feet well costs	$250.00
Fourth 50 feet boring, at $1.50	75.00
50 feet pipe, at $1.00	50.00
A 200-feet well costs	$375.00

The flow varies in different wells, bnt tbere are very few that will not irrigate 40 to 80 acres. The capacity may be atated at 40 to 200 acres. A flow of one and a half inch over the pipe is estimated to give 6,000 gallons per hour, or supply a town of 5,000 inhabitants, using 30 gallons each per day. The flow may he checked or controlled, to moisten or inundate.

Useful Information.

How to Do Up Shirt Bosoms.—Take two tablespoons best starch, add a very little water to it, rub and stir with a spoon into a thick paste, carefully breaking all the lumps and particles. Add a pint of boiling water, stirring at the sams time; boil half an hour, stirring occasionally to keep it from burning. Add a piece of "enamel" the size of n pea; if this is not at hand use a tablespoonful gum arabic solution, (made by pouring boiling water upon gum arabic and standing until clear and transparent), or a piece of clean mutton tallow half the size of a nutmeg, and a teaspoon of salt will do, but it is not as good. Strain tbe starch through a strainer or a piece of thin muslin. Have the shirt turned wrong sids out; dip the bosoms carefully in the starch and squeeze ont, repeating the operations until tho bosoms are thoroughly and evenly saturated with the starch; proceed to dry. Three hours before ironing dip ths bosoms in clean water; wring out and roll up tightly. First iron ths back by folding it lengthwise through ths center; next, iron the wristbands and both sides of the sleeves; then ths collar-band; now place the bosomboard under the bosom, and with a dampened napkin rub ths bosom from the top towards the bottom, smoothing and arranging each plait neatly. With a smooth, moderately hot iron, begin at top and iron downward, and continue the operation until the bosom is perfectly dry and shining. Remove the bosomboard and iron the frout of the shirts. The hosoms and cuffs of shirts, indeed of all nice, fine work, will look clearer and better if tbey are first ironed under a piece of thin old muslin. It takes off the first heat of the iron and removes any lumps of starch.

Danger from Lubricating Oils.—From a paper read by Prof. John T. Ordway, at a recent meeting of the New England Cotton Manufacturers Association, it appears that many of the oils used for lubricating machinery may be classed as dangerous, because when heated to a sufficient degree they throw off an inflammable vapor. In this respect it is claimed that some of the animal and vegetable oils are even more hazardous than those which are partially mixed with earth oils, and that the higher price of an oil is hy no means a guarantee of safety. An account was given of a fire last summer in the Bates Mills, Lewistown, Me., at which the flames, on reaching the weaving room, shot across it in all directions on a level of about five feet from the floor, and with sufficient heat to melt the lead counections to a gas meter located on the same plane of hight—from which the gas had been fortunately shut off—while a towel hanging two feet below this level was not scorched. This would seem to show that there was a body of inflammnhle vapor hangiug in the air, cast off by the oil used on the machinery.—*Scientific American.*

How to Smoke a Pipe.—A correspondent of the New York *Sun* gives the subjoined information: To those who are attached to the pipe, it may be a matter of interest to know how their last puff or draft of smoke may he as fresh as the first. It is well known that smoking in the usual manner the last portion of the tobacco becomes damp by presence of oil or nicotine drawn from the heated tobacco above, which causes a sickening and nauseating effect, hitter to the taste, unpleasant and unhealthy, as compared to the first half of a well-filled pipe. The following I have found to be effectual in giving me a good, fresh smoke from first to last: Place a small quantity of tobacco in the bottom of the bowl, light it, and when well afire, fill the pipe and before each draft give a light puff outward through the atem, which causes the tobacco to burn upward, all below being consumed. This is a sensible way of smoking the time-houored pipe.

A Warning to Amateur Chemists.—A recent fatal explosion of an oxygen retort in London, calls out the fact that two other accidents of the same nature have occurred within a few years. In both these casea binoxide of manganese was used as the source of the gas, and it was afterwards discovered that the oxide was adulterated, in one instance with soot, in the other with antimony sulphide, making mixtnres as dangerous as guupowder under the conditions required in the manufacture of oxygen. As this compound of manganese is very frequently used in the production of oxygen for experimental purposes, in the class room and elsewhere, it should always be tested beforehand for such adulterations.

Making Pencil-Marks Indelible.—Paper marks arc made indclible, says the *Papier Zeitung*, on paper prepared as follows: Any ordinary drawing-paper is slightly warmed and then rapidly and carefully laid on the surface of a bath, consisting of a warmed solution of bleached colophonium in alcohol until the entire surface is moistened. It is then dried in a current of hot air. The surface of the paper becomes smooth, hut readily takes the impression of a lead-pencil. In order to make the lead-pencil marks indelible, the paper is warmed for a short time on a stove. This method may prove valuable for the preservation of working drawings when a lack of time will not permit the draftsman to finish them in ink.

Coating Boilers.—Mr. Franz Beuttgenback gives the following recipe for the preparation of a coating for the inside surface of boilers to prevent the formation of scale: Gradually dissolve five pounds of a mixture of 25 parts nf colophonium, twn and one-half parts of graphite, and two and one-half parts of lamp black in 40 pounds of boiling gas tar, adding about one pound of tallow. The solution is diluted with about 50% nf the petroleum and applied in a warm stats. It has a pungent smell and should be put on rapidly, ths precaution of using closed lanterns being necessary. Its effect is to causo tho scalo to come off in large flakes when picked.

To Remove Ink from Carpets.—When freshly-spilled, ink can be removed from carpets by wetting in milk. Take cotton hatting and soak np all the ink that it will receive, being careful not to let it spread. Then take fresh cottou wet in milk, nnd sop it up carefully. Repeat this oporation, changing cotton and milk each time. After most of the ink has been taken up in this way, with fresh cotton and clean, rub the spot. Continuo until all disappears; then wash the spot in clean, warm water and a little soap, rinss in clear watsr, and rub until nearly dry. For ink spots on marble, wood or paper, apply nmmonia clear; just wetting the spot repeatedly till the ink disappears.

Straightening a Wooden Shaft.—Mr. D. A. Ammen, of Snowville, Va., senda the following: A wooden shaft can be straightened by taking hard acasoned wood and haking it in a stove or oven to get it to the smallest possible size. Dovetail it into the awagging side of the shaft, at the crookedest part. I straightened, perfectly, my bolt shaft, 22 feet long, in this manner, and have used it three years.

Rusted Steel Grates.—First the rusted steel should be washed with a solution of half an ounce of cyanide of potassium in two ounces of water. Then it should be cleaned by brushing with a paste made of hnlf an nunce of cyanide of potassium, half an ounce of castile soap, oue ounce whiting, and water aufficient to form a paste of the whole.

The Chinese make cracked porcelain by combining steatite with enamel. When put in the oven the mixture divides ao as to show a network, as it were, of cracks.

Good Health.

Contagion in Carpets.

Sewerage in these daya is receiving a fair share of puhlic and private attention, and the walls of houses, where contagious diseases have been, are very generally cleaned, whitewashed, or newly papered; but carpets are too often overlooked aa the carriers of disease. The truth ia that they, more than any article of furniture, more even than the walls of the room, gather and retain dust; and this dust, though chiefly inorganic and comparatively harmless, contains organic germs, which only need to be raised into the air and taken into the human economy to develop into active disease, creating, under favorahle circumstances, an epidemic. Dust usually considered as comparatively harmless, is a most fruitful source of catarrh and consumption. The irritation of the mucous membrane of the nose, throat and lungs, becoming chronic, leada to serious disease, that undermines health and destroys life.

Many women say: "If it were not for the sweeping of my carpets I could get along with housekeeping very well." Many women know from experience that aweeping is one of the great trials of the housekeeper's life, and that it causes much of "the weakness" among women. "Fore-warned is to be fore-armed." When we see the need of change, we are ready to accept the better methods. What shall these hetter methods be in relation to carpets and disease?

How easy carpets may convey contagion was proved by a case quoted by Prof. Tyndall, when he showed that a case of scarlatina, which was supposed by the physicians to be sporadic, was not so, but obtained by contagion. He said: "The question arose, how did the young lady catch scarlatina? She had come on a visit two months previously, and it was only after she had been a month in the house that she was taken ill. The housekeeper at once cleared up the mystery. The young lady, on her arrival, had expressed a wish to occupy a nice isolated room. In this room six months previously a visitor had been confined with an attack of scarlatina. The room had been swept and whitewashed, but the carpets had been permitted to remain."

The Value of Different Parts of Meat. Why is there so much difference in the nutritive value of the flesh of animals in different parts of the body? Answer—Flesh is composed of numorous huudles of minute tubes adhering together in a mass. These tubes are filled with the juices of the flesh. Now the quality of the flesh depends much on the juices, while the tenderness or toughness depends largely on these tubes, and these vary with the age and condition of the animal. In old or ill-fed animals the tubes are more than the juices, and the meat is tough. In youug animals it is the reverse. There is more nutriment in the flesh of animals not too young or too old, and neither too fat nor too lean.—*Dr. Holbrook.*

How to Make and Use Beef Tea.

An ordinary glass jar, such as is used in canning fruit, with the glass cover laid over the top, is very convenient, but like all other receptacles, must be thoroughly cleansed and aired after using before using again. Scrupnlous clennliness is very essential. If in great haste, the juiciest portion of the beef held over n brisk fire until heated, but not cooked, and then squeezed hard through a perfectly cleansed lemon-squeezer, is an excellent way, and makes a palatable article with the addition of a little salt. Salt is ths only seasoning usually allowed, but tbe patient's taste should be consulted, when not injurious. When ths patient tires of these modes, scraps with a sharp knife enough lean, juicy beef to fill a pint bowl, add a little water, cover close and set in the oven and let it bake slowly. When about half done remove the cover and let it brown a little, then cover again nnd let it cook a while longer. Beef tea made after this last mode has been accepted in cases where all other ways have failed.

Never approach a patient with a spoon in the hand when about to give nourishment. Put just what yon wish taken, and no more, in the daintiest and prettiest teacup in the house. Have tbe tea of just the right temperature, and let the patient drink it from the cup, but remove the cup from the room as soon as used; and, we would add, wash, scald and put it in its proper place. When more tea is needed, take another and entirely different cup. This seem a little thing, but the comfort of the sick must depend largely on little things, and who shall blame them if sometimes fanciful or unreasonable?

Useful, if not New.

Tho following simple rules for preserving health and for promoting personal comfort, if not new, are none the less important to every one:

The object of brushing the teeth is to remove the destructive particles of food which, by their decomposition, generate decay. To neutralize the acid, resulting from the chemical change which such particles as are not removed undergo, is the object of dentifrices. A moderately stiff brush should be used after every meal, and a thread of silk floss or India rubber passed through between the teeth to remove particles of food. Rinsing the mouth in lime water neutralizes the acid.

Living and sleeping in a room in which the sun never enters is a slow form of suicide. A sun bath is the most refreshing and life-giving bath that can possibly be taken.

Always keep the feet warm, and thus avoid cold. To this end, never sit in damp shoes or wear foot coverings fitting and pressing closely.

The best time to eat fruit is half an hour before breakfast.

A full bath should not be taken less than three honrs after a meal. Never drink cold water before bathing. Do not take n cold bath when tired.

Keep a box of powdered starch on the washstand; and after washing, rub a pinch over the hands. It will prevent chapping.

If feeling cold before going to hed, exercise; do not roast over a fire.

Starvation in the Nursery.—In an article headed "Starvation in the Nursery," the London *Lancet* calls attention to what it says is a fact established by daily experience—that large numbers of persons occupying decent positions in society systematically starve their children, in respect of that article of food which is the most essential to their nutrition. Even to very young and fast-growing children they give cocoa with water, and not always a suspicion of milk; corn-flour with water just clouded with milk; tea, oatmeal, baked flour, all sorts of materials, indeed, as vehicles of milk, hut so very lightly laden with it that the term is a sham. The consequence of this misplaced economy is, that there are thousands of households in which the children are pale, slight, unwholesome-looking, and, as their parents say in something like a tone of remonstrance, "always delicate." Ignorance, no doubt, is often the cause. The parents do not know that, supposing there were no other reason, their wisest economy is to let their growing young ones have their unstinted fill of milk, even though the dairyman's bill should come to nearly as much as the wine merchant's in the course of the week. But in many, the medical paper is of opinion, the stint is a simple meanness, a pitiful economy in respect of that which, it is supposed, will not be open to the criticism of observant friends.

Nuts.—Are nuts wholesome? Nuts are very rich food, containing much oil, in such a state that it is not easily acted on by the gastric juice unless minutely divided before heing passed to the stomach. Thoroughly chewed, however, they are wholesome for persons with good stomachs. Children may eat nuts freely to advantage, but care should be taken to choose fresh ones. Stale, old, overdried nuts are very indigestible and injurious.

Keep Active.—Never sit down and brood over trouble of any kind. If you are vexed with yourself or the world, this is no way to obtain satisfaction. Find yourself employment that will keep your mind active, and, depend upon it, this will force out unwelcome thoughts,

TABLE OF CONTENTS.

GENERAL EDITORIALS.—A Practical Traction Engine; The Bodie Claims, 1. The Week; Arizona; The Metallurgy of Mercury in California; Automatic Rotary Gas Mixer, 8. A Kingdom for a Process; The Great Gray Owl; Is there an Active Volcano in the Moon? 9. Patents and Inventions; Notices of Recent Patents, 12.
ILLUSTRATIONS.—An Improved Road Locomotive or Traction Engine, 1. Harlan's Buzzard, 6. Great Gray Owl; A Volcano in the Moon, 9.
MINING STOCK MARKET.—Sales at the San Francisco, California and Pacific Stock Boards, Notices of Assessments, Meetings and Dividends, 4.
MINING SUMMARY from the various counties of California, Nevada, Arizona, Colorado, Idaho, Montana, New Mexico, Oregon and Utah, 5.
OUR CABINET.—Garnet, 9.
NEWS IN BRIEF on page 12 and other pages.
CORRESPONDENCE.—Scenes in the High Sierra Back of Yosemite—Continued, 2.
MECHANICAL PROGRESS.—Iron in Car Construction; Testing Boiler Iron; What is Steel? Machine for Measuring Superficial Area; Improvement in Soldering Irons; Correction, 3.
SCIENTIFIC PROGRESS.—Experimental Determination of the Velocity of Light; Cast Manganese; Vegetable Albanism; Barcenite—A New Antimonate; Disease of Chestnut Trees; Heat-Conducting Power of Rocks; A Quartz Thermometer, 3.
THE ENGINEER.—The Effect of Brakes on Railway Trains; Improvements on the Kanawha; Improvement in our Ship-Building Industry, 6. Bridging the Bosphorus; The Gibraltar Tunnel; The St. Gothard Tunnel; Engineering, 7.
USEFUL INFORMATION.—How to do up Shirt Bosoms; Danger from Lubricating Oils; How to Smoke a Pipe; A Warning to Amateur Chemists; Making Pencil-Marks Indelible; Coating Boilers; To Remove Ink from Carpets; Straightening a Wooden Shaft; Rusted Steel Grates, 8.
GOOD HEALTH.—Contagion in Carpets; The Value of Different Parts of Meat; How to Make and Use Beef Tea; Useful, if not New; Starvation in the Nursery; Nuts; Keep Active, 7.
MISCELLANEOUS.—A Snake River Debate; Gold Sands, 2. Mines and Works of Almaden—No. 10; A New Indicator; Harlan's Buzzard, 6.

NEW ADVERTISEMENTS.

Boswell's Combined Heater, Cooker, Baker, Clothes and Fruit Drier. Coin Silver Tableware Given Away, Eagle Gold and Silver Plating Co., Cincinnati, Ohio.

The Week.

Resumption of specie payments is now guarded by law. No great and exciting catastrophe occurred on the day fixed for resumption. Some people seemed to think there would be a grand movement of some kind—of what kind it is hard to imagine. Sherman was to be in New York to see resumption commenced, rumored those visionaries. But here we are on a foundation of golden honesty, and people do not realize that anything startling has occurred. Nor will they until a year or so brings unknown prosperity, and the students of economy begin to point back to January 1st, 1879, as the beginning of the "golden era." Among the events of the week is another, which reflects more credit upon the popularizing, anti-speculator policy of Sherman. Gold is to be purchased at Helena, Montana, directly from the miners and others who have it to sell, in exchange for greenbacks at par. The Department is buying gold on similar terms at Charlotte, N. C., at Boise City, and Denver. The startling claims on the Bodie mining property will be referred to in another column. As far as present developments go, the whole affair shows a rather astonishing carelessness and neglect on the part of men who have been thought capable of taking care of themselves.

THE recent discoveries of rich silver mines near Tucson is creating excitement among our miners.

THE Reno *Journal* reports encouraging news from the Mansanola mines.

Arizona.

The event which promises most for the New Year is the opening of Arizona by the Southern Pacific railroad. The whole commercial world will be enlivened by it; the mining industry in all its branches will be enlarged and strengthened; new problems will be brought more forcibly than ever before our people—problems to test the ability of our engineers, both those who bear the transit and leveling rod, and those who map out our courses in legislative halls.

"Over-production" is the cry among our manufacturers to-day. The spectacle of England, shutting down her factories and turning thousands of employees out into the cold of an unusually severe winter, is fraught with inevitable lessons. And we all know that we do not have to go across the Atlantic to be reminded that markets are stagnant. In the heat of competition, and the clatter of new labor-saving machines, men have made more than they can sell. And now every eye is straining to discover some outlet, be it ever so small, through which to crowd the stock from bending shelves and overfull warehouses.

And not a few faces are turned towards Arizona. Now Arizona is not a gigantic glutton, to swallow the surplus of the world. She is not yet developed sufficiently to send in lengthy orders to the merchants and manufacturers of her sister States and Territories. And were she so, her spirit is too plucky to admit of long dependence upon others. But these are facts: Arizona has vast territory unsettled, and great resources undeveloped. She has, moreover, an energetic population within her borders, who realize the richness of her possessions, and have a press through which they are not slow in publishing them abroad. Add to this a railroad, pushing up one of her richest valleys, and symptoms of new wagon roads from the principal towns to join with it. Then we have all the requisites for a considerable demand upon outside markets, for at least a space of several years. Arizona will soon stand alone. The few Mormon shuttles on the Colorado Chiquito will in short time grow into a woolen mill. Then no longer need the sheepraiser pay freights out on his wool, and freights in again on his shirts and stockings. Already the home product of flour is sufficient to have established a reputation among the camps. It will not be a great while before the furnaces in the mountains will be made of Arizona brick; and who shall say that the mill-machinery shall not be forged with Arizona coal, if not made of iron mined within the Territory. But for the present, Arizona must draw largely from California, and through California from the East. San Francisco foundries must do most of her iron work; California mills must grind her flour; and houses in our cities must import most of her manufactured goods of all classes. This is how Arizona, with a railroad, will make herself felt in the commercial world.

That the opening up of Arizona will enlarge and strengthen the mining industry, need not be enlarged upon. Arizona is thought of in the outside world as pre-eminently a mining country. The fame of her mines has gone forth until it is almost forgotten that she has verdant valleys for agriculture and hillsides to support a large grazing industry. It is not necessary at this late hour to detail the silver and gold regions, the mines of copper, lead, iron, cinnabar, and coal. What the people want to know now, is whether there will be food for the miners, and any reasonable supply of the comforts of life. The Arizona press will do more good by attending now to these matters than by dwelling on the mineral resources, which are already widely known and undoubted. Assure the miner that he will not starve, and he will try his luck despite stories of desert and of hostile Indians. This assurance comes when Arizona is vitally connected with great centers of supply. Exploration of little-known districts may be now looked for. New discoveries will be reported every day, as they have been lately almost every week. And upon the track of discovery, capital may now follow with more confidence than ever before, bringing all the good things of capital, roads and smelting works and mills.

The growth of Arizona will bring up many important problems before the United States. Immense engineering feats will be dwelt upon in council if not carried out. The irrigation of the "deserts" is a question that is nearer the people to-day than ever before. But there is another question of more vital and general importance; it concerns our relations with Mexico. Mexico is attracting no little attention to-day. The excursion of Eastern traders shows both the fact and its significance. Mexico has resources, if they are almost entirely latent, and held back by revolutionary laws and all their attendant evils. It will profit us to have closer relations with her. That is what the New Orleans excursion means. It is now settled that our trade with Mexico cannot grow without an international railroad. Is this railroad to go down through Texas, New Mexico or Arizona? We think the question is almost answered in the progress of the Southern Pacific. Our coast is more nearly related to Mexico than any other part of the country. Every effort should be made to turn the prospective trade into our channels. So Arizona shall prove not only a desirable end in herself, but a means to an end as well.

The Metallurgy of Mercury in California.

We acknowledge the receipt from the author, M. Georges Rolland, Ingenieur an Corps des Mines, of an interesting monograph with the above title, reprinted from the publications of the *Societe d'encouragement pour l'industrie nationale*. The article is the result of a tour through the quicksilver mines of California during the year 1876. The author promises that he will shortly treat of the "Deposits of Mercury in California," in an article to appear in *Annales des Mines*. He promises at the same time to publish the statistics which he gathered in his trip, as to the phases of production in California, the consumption of it on the Pacific coast, its exportation to China, to Mexico, etc., and finally the fluctuations of the price of the article in San Francisco.

The author gives to the Americans the credit of having invented a great number of new arrangements, some of them very ingenious. The reason of this is, of course, as the author claims, partly due to the great cost of manual labor, and also to the recent fall in price of the article itself, which requires the strictest economy in its production. He, however, very justly criticises the neglect of the custom of carefully taking samples and making assays of all the ores treated. New Almaden, as far as we know, is the only mine at which this was ever attempted in anything like a systematic manner, and here we regret to say, it was not continued. Although the careful taking of samples, and the making of assays of an ore costs considerable care and money, without adding to its richness, still the exact knowledge of condition of the whole metallurgical operation which is thus obtained, the control it gives in case of otherwise undiscoverable losses from accident or theft, etc., is certainly worth more than 10 times its cost. This is more particularly so in the case of a valuable metal like quicksilver. It is to be hoped that our quicksilver metallurgists will no longer thus work in the dark. There are many interesting and technically valuable questions that can be settled in no other way.

In the article of which we speak the works of only the three principal mines, are treated at any length: those of New Almaden, Redington and Sulphur Bank. As we have neither time nor room for the whole article, we can only speak of some of the principal points.

Retort furnaces, in which cinnabar is heated with lime, are generally abandoned in California, and are only used in the treatment of mercurial soots. The intermittent furnaces hitherto in use in California are generally replaced by continuous furnaces with improved systems of condensation. Continuous and automatic furnaces have been invented for fine ore, thus enabling the expeditious treatment of fine ore, without manufacturing it into bricks.

For the treatment of coarse ore, the author speaks in the following terms of the improved iron-clad Idria shaft furnace in use at New Almaden:

"The movement of the ore and the gases in the furnace in opposite directions, is a rational idea. The gases and vapors escape at the top at a low temperature. The roasting and the distillation of mercury take place at the lower part. The furnace, as its name indicates, is surrounded by a metallic casing." * * * *

"It may be affirmed that the loss in the treatment of ores in this furnace, at New Almaden, is less than that of any other establishment in California."

The furnace of Livermore, at the Redington mine, and that of Hutner and Scott at the New Almaden, are described in full. We would give the relative costs of treatment in the various styles of furnaces as furnished in the articles, except that such could not be made the basis of any comparison without a knowledge of the richness of the ores (treated), and the exact loss during the operation.

The arrangements for condensation, particularly those of New Almaden and Knox and Osborne, are described in full. The arrangements at New Almaden show the greatest amount of care and forethought in their construction. There are first large brick chambers to take the hot gases and vapors, and to allow their expansion and cooling. They then pass into the iron condensers of Fiedler, cooled by water upon the top, and by hollow partitions containing the same material. Thus cooled, the vapors pass into the condensers of wood and glass, invented by Fiedler & Randol, and thence by an extensive system of flues and chimneys, to the top of the neighboring hills.

In 1876 the author states that the furnaces of the Sulphur Banks produced a greater quantity of mercurial soot than any other establishment in California. This amount was greater than 1.5% of the ore treated. The cause was the imperfect drying of the ore before roasting, and the partial roasting. The soot contained not less than 40% of mercury on the average; contained much sulphur, partly fine, partly in the state of sulphide of mercury. The ore at the Sulphur Bank, very much broken, very wet, very bituminous, and above all supersaturated with sulphur, offers, it is true, special difficulties to the operations of drying and roasting, and its low contents hardly justify the expense of a preparation which would be very great.

THE Aqua Fria smelter has just turned out from Silver Belt ore seven tons of base bullion, worth perhaps $5,600.

Automatic Rotary Gas Mixer.

The electric light has so many chances of success, that attention is being called to all plans that may aid the gas companies in making use of their product for heating and cooking purposes. In 1875 an automatic rotary carbureter was patented by T. A. Stombs, through the MINING AND SCIENTIFIC PRESS Patent Agency, which in this connection demands special notice now.

The machine consists of a cylinder divided into two apartments by a diaphragm parallel to the base. In each apartment is a fan wheel, which turns upon a shaft passing through the axis of the cylinder. The fans of the wheels are covered with blanket or other suitable material, when the machine is to be used as a carbureter. The blanket is arranged on a frame, so as to pass from the circumference to the center, on one fan, and back to the circumference and over the next fan, and so on. When making heating gas, no blankets are necessary, the bare fans being sufficient. Water, or, if the machine is to be used as a carbureter, gasoline or some other suitable material, is put into the larger apartment of the cylinder, which rests horizontally, and rises to a certain hight, regulated by an automatic valve.

The air is admitted near the shaft, but is conducted by a pipe up to a point above the surface of the liquid, where it is discharged into the cylinder. The wheel revolving, the fans catch the air, and tend to force it beneath the surface of the liquid. However, the fans are slightly inclined on the shaft, so that as each fan comes around the edge nearest the inlet strikes the liquid first, and continuing to pass downward, pinches the air, and finally forces it out towards the diaphragm, near which is an outlet.

The smaller apartment of the cylinder, on the other side of the diaphragm, contains the driving wheel. This is a fan wheel arranged so that air or gas under pressure will revolve it, the gas being finally forced out through a pipe near the diaphragm, and parallel to that through which the air escapes from the other apartment.

Now it is suggested that this apparatus be used for mixing air with gas that is to be employed for heating or cooking. The machine may be connected with the gas pipes between the meter and the point of consumption, no changes being necessary in the present system of delivery. The amount of air necessary for a given amount of gas can be regulated by governing the relative sizes of the two apartments in the cylinder. It is claimed that gas taken into the driving apartment at two inches water pressure, will run the machine. As the gas revolves the driver, the fan-wheel in the other apartment will suck in air and deliver it through the pipe parallel to the gas pipe. The air and gas in correct proportions will thus proceed in separate pipes to the point of consumption, where at the proper time they will mix. The machine, it is said, may be built to supply any number of burners, from one to 1,000, and at all times producing a mixture containing the desired proportions of gas and air.

And now as to the economy of using heating gas as a fuel, in the parlor grate or in the kitchen stove. Suppose the mixture is to contain four parts of air to one part of coal gas. The cost of 1,000 cubic feet of the mixture would be as follows:

1,000 feet coal gas at works.....	$2.25
4,000 feet air at machine.....	—
5,000 feet heating gas.....	2.25
1,000 " " "	45

The heating gas could, then, be delivered to the consumer at 45 cents per 1,000 feet. We will compare this now with the cost of coal as a fuel.

To keep a fire in a grate for 6 hours in 24 would require 10 lbs of coal. Say that the coal used costs $9.00 per ton, or 45 cents per 100 lbs, 10 lbs would cost 4½ cents. The fire would cost per month $1.35.

In using gas suppose three 2-foot burners were employed, consuming together 6 feet per hour, 36 feet per 6 hours, or 1,080 feet per month. This, at 45 cents per 1,000 feet, would cost 48½ cents per month. This shows a saving in favor of gas of 86½ cents per month per grate, or 64%.

The inventor says, that the gas can be used to the full capacity of all the burners, or, of only part of them. The consumption can be controlled just as it is in the use of ordinary gas. There is no soot, ashes, dirt. The combustion is perfect, so no flues are necessary, and in the place of them in a grate, may be set a bright metal reflector, to send the heat out into the room. In the ordinary grate 50% of the heat goes up the chimney with the smoke.

With this machine, heating gas can be made from gasoline, or even from heavy unrefined coal oil at a still less cost. For instance, one ton of coal worth $10 per ton will produce 10,000 feet of gas. The same amount of gas may be produced by 50 gallons of coal oil, which, at 16 cents per gallon, would cost $8. One thousand feet of this gas would cost then 80 cents. One thousand feet of heating gas made from it, by mixing four parts of air with one of gas, would cost 16 cents; 10,000 feet would cost $1.60, which is a saving of $8.40 for every ton of coal used.

Metallurgy and Ores.

Nevada Metallurgical Works,

No. 23 STEVENSON STREET,
Near First and Market Streets.

Ores worked by any process.
Ores sampled.
ASSAYING in all its branches.
Analysis of Ores, Minerals, Waters, etc.
WORKING TESTS MADE.
Plans furnished for the most suitable process for working Ores.
Special attention paid to Examinations of Mines; plans and reports furnished.

MINING ENGINEER and METALLURGIST.

P. O Address: ALAMEDA, CAL.

SAN LORENZO, December 6th, 1877.
MESSRS. DEWEY & CO.—*Gentlemen:* I received the Letters Patent for my invention on the 5th inst., and beg to thank you for the gentlemanly and business-like manner in which you have dealt with me from the beginning of my application. I shall always feel it a pleasure to recommend you to all I come in contact with who need Letters Patent. Respectfully, WM. DALE.

Ingersoll Rock Drills.

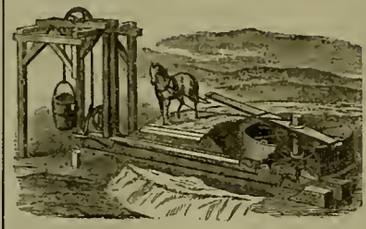
In use in the largest and best Mines of the Coast.

HAS AUTOMATIC FEED.

Has less Repairs.

Is Lighter and more Easily Adjusted than any other Drill.

Our DRY AIR COMPRESSORS are the most Economical Compressors in the Market.



MINERS' HORSE-POWER.

This Power is especially adapted to working mines, hoisting coal or building material, etc. It will do the work of a Steam Engine with one-tenth the expense. One Horse can easily hoist over 1,000 pounds at a depth of 500 feet.

The Power is mainly built of wrought iron, and cannot be affected by exposure. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

REYNOLDS, RIX & CO., 18 & 20 Fremont St., San Francisco.

Office, Room 28, Stevenson's Building, S F.

DEFLECTORS,

Or Perkins vs. Hoskin.

W. H. PERKINS has for nearly two years been threatening orally and through the Press to prosecute all persons using my Patent Deflecting Nozzle, but for *good reasons*, has failed to come to time. I want miners to understand that Deflectors are still manufactured and sold, and that I will defend all suits and assume all responsibility. Mr. P. will confer a favor if he will carry out his threat, as it will afford me the opportunity I desire to again try the case, and he can rest assured that *professional dodges* will not again be allowed to *temporarily* thwart the ends of justice.

I feel confident that the Supreme Court of the United States will ultimately decide in my favor. The superiority of my invention is shown by the means which Mr. P has resorted to in trying to stop my sales. Mr. P. has so degraded himself as to circulate statements which he knows to be *false and malicious.* Notwithstanding the great number of my Deflectors in use, I have heard of but one accident, and this was caused by the breaking of the iron lever from a defect in the material and great carelessness in use. This circumstance Mr. P. has magnified into several deaths and numerous accidents. I refer to the following owners and Managers for testimonials as to safety and efficiency. Some of them have used and discarded Mr. Perkins' device in favor of my much superior one. Messrs. Gould, Gold Run, using 4; Spaulding, Dutch Flat, on different mines, 12; Stone, Gold Run, 2; Morgan, Little York, 6. Bisbee, Iowa Hill, 2; Briere & Wheeler, Bath, 2; Mr. Gillvary, Forest Hill, 4; Atkins, Weaverville, 2. I could mention scores of others, but these are sufficient.

Mr. Perkins' device is an infringement on a patent owned by Mr. Craig, who is about to institute legal proceedings to protect his rights. Miners are advised to stand from under. A word to the wise is sufficient. R. HOSKIN,

Manufacturer of Machines for Hydraulic Mining. Address, No. 29 Garden Street, San Francisco, or Empire Foundry, Marysville, Cal.

Engraving done at this office.

CAUTION

To Hydraulic Miners.

The public generally and Hydraulic Miners especially are hereby notified that any parties making or using the contrivance known as the HOSKIN DEFLECTOR will be prosecuted to the full extent of the law, said machine having been declared by the U. S. Circuit Court an infringement upon my patent, the

Bloomfield Deflecting Nozzle.

The public are also cautioned against using the Hoskin Deflector because of its danger to life and limb, this device having already occasioned several deaths and other serious accidents. The BLOOMFIELD DEFLECTOR is entirely safe, its two and a half years use without accident, as well as its construction, proves it to be a reliable contrivance.

Any parties wishing to purchase the right to use these Deflectors can do so by applying to the undersigned,

HENRY C. PERKINS,
North Bloomfield, Nevada Co., Cal., October 1st, 1878.

Engraving Superior Wood and Metal Engraving, Electrotyping and Stereotyping done at the office of the MINING AND SCIENTIFIC PRESS, San Francisco, at favorable rates. Send stamp for our circular and samples.

A CHANGE of management is ahout to occur in the hranch of the Bank of British Columhia at San Francisco.

THE people of Ceara, Brazil, are dying at the rats of 600 daily of small-pox, and the distress is appalling.

IT is stated that 40% of the Bosnians who have returned home will perish hefore spring unless the weather moderates.

MONCASI, who attsmpted to kill King Alfonso, has heen finally coudemned to death hy the Supreme Court of Justice of Spain.

SEVEN immense electric lanterns have heen ordered at Paterson, N. J., by the Russian government, for use on men-of-war.

FLOOD, of the honanza firm, sent Christmas checks for $1,000 each to the San Francisco orphan asylums, and of $500 each to the henevolent societies.

A TRAIN was attacked hy robhers between the City of Mexico and Vera Cruz, who killed the baggage-master, wounded the conductor and escaped with $27,000 in silver.

The Pig Iron Market.

William Jeffray, metal and coal hroker, 204 California street, seuds us his review of the year 1878, from which we extract the following: In Jauuary, Scotch, soft, was quoted at $30 to $31, the highest duriug the year. The lowest quotations were in Octoher, viz: $25 to $26.50. Decemher quotations were, $26 to $27. English and American, white, show a constaut falling off, from $28 in January, to $25.50 in October, November and December. American, soft, was $28 to $29, in January; in Novemher, it was $22 to $26; Decemher, $24 to $26.

I find the stock of pig iron on hand January 1st, 1879, in all, 14,370 tons, as per statement given helow, heing 2,995 tons less than the stock on hand January 1st, 1878.

Stock of pig iron on hand January 1st, 1878, 17,365 tons. Importatious of 1878—Scotch, soft, 2,107 tons; importations of 1878—American, eoft, 7,235 tons; importations of 1878—American, white, ——; importatious of 1878—English, white, 1,705 tons; total importatious of 1878, 11,047 tons. Grand total, 28,412 tons.

The ahove figuree show a decreased cousumption this year as compared with last of 1,521 tons, viz: 3,312 tons of soft Scotch, and increase of 430 tons of white, and 1,355 tons of American soft.

The importations of 1878 show a decrease of 6,425 tons as against the importations of 1877.

TRANSMISSION OF HEAT BY STEEL AND IRON PLATES.—In a letter addressed hy Mr. John Collins to *Engineering*, that gentleman gives the following data derived from experiments made to ascertain the relative heat conductivity of iron and steel plates. The apparatus consisted of exactly similar plates of steel or iron 11⅝ square, .23 in. thick, supported on glass legs, heated hy a Bnnsen hurner consuming equal quantities of gas, maintained at 2 iu. pressure coustantly, aud a hasis 3 in. in diameter placed iu the center of the plate, containing mercury iu which a delicate thermometer was immorsed. The temperatare of the mercury was theu raised from 20° C. to a 160° C., and relativo times uoted. The average gain in time of steel over iron plates of equal thickuess is 13%. When the relative thickuess of tho plates as used in hoiler huilding is taken, this gives au average gaiu of ahont 20%. Iu steam hoiler trials, where hoilers are similar in all respects, say thickuess and material, the actual gain iu working 20 days of 12 hours each shows actual evaporative power of 20% in favor of steel. In another series of a similar nature hy Stuckentholtz, the results gave 19.6% and 20.8% in favor of steel.

Improvement in Iron Smelting.

The Horicon Iron Co., of Tioonderoga, N. Y. according to the *Polytechnic Review*, Nov., 1878, is sngaged in manufacturing, hy a modification of the Catalan force process, hlooms which are said to prove equal in uniform excellence to the Swedish and Norway irons. The peculiarities of the process are chiefly the two following: The ors, instead of heing thrown cold upon the forge-fire, descends through a retort or chamher in the rear, into which it has heen charged, mixed with charcoal braize. By the time it has reached the bottom of this chamher, and is raked forward into the fire, it is not only thoroughly heated, hut is also reduced to metallic sponge. The chamber is heated hy the flame-products of the forge-fire, and also by the combustion of carhonic-oxide, generated from the forge and hraize, and escaping through the ports in the wall, to hurn in the surroundiug flue. This arrangement is the first peculiarity of the process. The second is the charging of the very fine ore-dust into another chamher where it is pre-heated, and then taken by a screw-conveyor and carried through a hollow journal and a small gas-pipe into the tuyere, which conveys it into the forge-fire and deposits it upon the surface of the loup. In this way a great loss of fine ore is avoided, and a saving of fuel is effected. There is still another peculiarity in these works, affecting the suhsequent manipulation of the blooms. The loup is introduced into a Sweet's furnace, and thoroughly heated hefore shingling. In this way, it is claimed, a more complete removal of cinder, etc., is secured. Certainly the hlooms and billets which we saw treated exhihited great solidity and uniformity under the hammer. The capacity of the four fires now in operation is abont four tons daily—eight loups heing taken out of each during the twenty-four hours. The works have heen hut a few days in operation on this plan, but the experiment promises to he successful, and, if commercial results warrant, the capacity will he at least douhled. The ore now used is the Bessemer magnetite of the Crown Point Iron Co.; hut the Horicou Co. possesses extensive deposits of its own, upon which it cau fall hack if necessary.

Bullion Shipments.

Since onr last issue, we have noticed the following shipments of hullion:

Arizona.—Mineral Park Mill, Mohavs couuty, $4,400. Tiptop, $23,000.

California.—Bodie, Dec. 23d, $12,300. Extra, Dec. 22d, $1,400; Dec. 25th, $1,660. Standard, Dec. 25th, $17,750.40.

Colorado.—The Black Hawk *Post* says: The hullion shipment from Gilpin county hy the Union Pacific express company, for the month of November, is as follows: From Hill's smeltiug works, gold, $90,000; from the mills, gold, $105,700, aud silver, $103,800.

Idaho.—Silver City, Dec. 15th, $9,830.27.

Nevada.—Alcxander, Dec. 24th, $9,556.02; California, Dec. 28th, $121,335.49; total to date, $638,806.72. Eureka—*Sentinel*, of Dec. 25th, reports a shipment of $1,311.98. Hillside, Dec. 31st, $5,219.00. Jefferson, Dec. 23d, $2,169.87. Leopard, Dec. 29th, $8,300. Manhattan, Dec. 23d, $11,000. Navajo, Dec. 25th, $5,267.78. Northern Belle, Dec. 25th, $2,802.58. Trojan, Dec. 27th, $10,043.04; total this month, $18.221.24. Tybo Con., Dec. 25th, $3,947.31.

Utah.—Christy Con., Dec. 27th, $6,093; Ely Mill, Dec. 21st, $900; Dec. 24th, $1,100; Ontario, Dec. 20th, $2,568.57; Dec. 21st, $2,732.25; Dec. 23d, $5,112.07; Dec. 24th, $2,348.83; Silver Reef, Dec. 20th, $5,526.31; Dec. 24th, $11,515.59; Dec. 26th, $4,399.92. The *Miner* gives the total shipments hy Wells, Fargo & Co., for the week ending Dec. 21st, at $22,073.80.

TEMPERING NICKEL.—Nickel, like iron, ie magnetic, sufficiently ductile to he forged and drawn into slender wire. Its point of fusion is very high, and if melted in a *brasque* crucible it yields a homogeneous regulus of a silvery whiteness, containiug carhon. M. Boseingault has examined whether nickel, like iron, when carhureted, is capahle of being tempered and acquire elasticity, and whether it rendere steel less susceptihle of oxidation. The result was decidedly negative except that alloys of iron and steel, with large proportions of nickel, 30% and upward, resist the oxidizing action of air aud water.

THE Highhridge mill works up the ore to a trifle over 95% aud the yield per tou exceeds expectatious.

DURING this year 313 mining claims have heen recorded in the Recorder's office of Bodie district.

H. J. T. SCHEEL has taken out of his little gold vein in Gold Canyon, Lyon county, Nev., 23 tons which has yielded $18,000.

THE strike in tho Last Chance mine is one of the richest ever made iu Silver Reef district.

THE Crosscut, in Humhug district, is developing one of the largest aud richest mines in Yavapai county.

PATENTS AND INVENTIONS.

List of U. S. Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

By Special Dispatch from Washington. D. C.

FOR THE WEEK ENDING DECEMBER 17TH, 1878.

CLIPS FOR ROPE TRAMWAYS.—Andrew S. Hallidie, S. F.
BREECH-LOADING FIRE-ARMS.—Julius Bluemel, S. F.
ORE STAMPS.—Stephen Kendall, Jackson, Cal.
WAGON JACKS.—Harris H. Margeson, East Oakland, Cal.
WINDMILLS.—Thomas E. Martin, San Joss, Cal.
BITTERS.—Trademark—Charles R. Burrags, S. F.
CHOCOLATE, BROMA AND COCOA.—Tradsmark—Domingo Ghirardelli, S. F.

Notices of Recent Patents.

Among the patents recoutly obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Ageney, the following are worthy of special mention:

DREDGING AND DITCHING MACHINE.—Daniel Bridges, Yoncolla, Douglas county, Oregon.—Dated Dec. 3d, 1878. The invention is an improved drcdging and ditching machine, and the improvements consist in a novel combinatiou of mechanism hy which the inventor is enahlcd to cut out and lift the earth by the vertical action of the dredging bucket; and in certain details of construction, the machine can he made on a small scale to he worked by hand for ditching purposes or may he made large to he worked hy steam power for reclamation purposes. It will operate in any earth stiff enough to hold together without falling between the forks of the grapple. For softer matsrial a plato of metal is used instead of forks. Ths device is intended more particularly to construct ditches or dikes on marsh swamps, tule or tide lands where there is little or no fall to the grouud, and where the marshy character of the soil is such as to preclude the use of horse power. The devics is used to hest advantago on a scow, being operated by hand or steam power. It has heen practically and successfully tested in Oregon hy the inventor.

SPARK ARRESTER.—J. H. Bartlett, Woodland, Yolo county.—Dated Dec. 10th, 1878. This invention relates to a novel apparatus to he applied to the smoke stacks of hoilers and engines, whereby the inventor is enahled to arrest the sparks which would ordinarily he thrown out hy the force of the exhaust steam or draft, aud which are dangerous when used in the harvesting field or among stuhhle, or in any place where there are combustihles which are liahle to hecoms ignited. It consists in the employment of spiral or screw-shaped directing wings having their axis placed eentrally in the stack, and these wings are bent over at the top, so as to form a sort of cup, into which the sparks, following the incline of ths screw, will strike and he conveyed hy pipes hack into the smoke hox.

PULVERIZING BARREL.—John C. Senderling, San Francisco.—Dated Dec. 3d, 1878. This invention relates to certain improvements in crushing and pulverizing barrels or that class of apparatus in which halls, rollere, ehoes, hammers, etc., are employed to crush and pulverize rock within a rotating cylinder or harrel. It consists in the employment of a iron rotating, etationary or adjustahle shaft, passing through hollow trunnions of the harrel, and having arme attached for the purpose of holding rollere or shoes in position. The said rollers or shoes may thus he held at a certain point, and as the ore is fed into the harrel it passes between the rollers or shoes and the inner periphery of the cylinder or harrel. The pulverized ore will escape through perforations or slots in the dies and from thence through the enclosing screens, while any particles not crushed sufficiently free will he returned to the cylinder.

LIGHT WEIGHT HORSE FORK.—Byron Jackson, Woodland, Yolo Co., Cal.—Dated, Dec. 3d, 1878. This inventiou relates to certain improvements in devices, known as horse forks, such as are employed to handle headed grain, and hay or straw. It eonsists in a novel eonstruction of the head in two pieces, and a light frame work having as many hars as there are tines on the fork, the two outeide hars heing united at one end, and diverging from each other at the opposite eud, to secure the outside tines. The other hars of the frame receive the inner tines at one end, and are united at the other end to the outside bars. One end of each of the hars of this frame is locked hetween the two head pieces, hy the tines passing through them. The tines heing shouldered ou a light frame brace on one side, aud a nut screwed down on the other. The braces are cast rolled to a bar of the frame, thus hringing the strain of each tine lengthways with each har of the frame. There is then no twisting etrain on any portion of the frame or head, as ie the case in the old methods of using a single head piece and clamping the lifting arms to it hy means of east or wronght iron hands. By this construction the weight is reduced nsarly one-half, while the same strength is retained.

AIR VALVE ATTACHMENT FOR SEWER TRAPS.—P. F. Morey, S. F.—Dated November 19th, 1878.—This valve is intsnded as a stop to prevent the return through the connecting pips of sswers of noxious vapors. We illustrated and described it in detail in the MINING AND SCIENTIFIC PRESS of March 9th last. It has heen extsnsively introduced here hy the manufacturer, David Bush, 27 New Montgomery street.

FRESH attractions are constantly added to Woodward's Gardens, among which is Prof. Gruher's great educator, the Zoographicon. Each department increases daily, and the Pavilion performances are mors popular than ever. All new novelties find a place at this wonderful resort. Prices remain as usual.

SETTLERS and others wishing good farming lands for sure crops, are referred to Mr. Edward Frisbie, of Anderson, Shasta County, Cal., who has some 15,000 acres for sale in the Upper Sacramento valley. His advertisement appears from time to time in this paper.

EXAMINE the accelerative endowment plan, as originated by the Mutual Benefit Lifs Insurance Co., of Newark, Nsw Jersey. Assets, $30,533,429.94. Lewis C. Grover, President; L. Spencer Cobls, Vice-President; Benjamin C. Miller, Treasurer; Edward A. Strong, Secretary; Bloomfield J. Miller, Actuary. Send for circulars to James Munsell, Jr., agent of insured, 224 Sansome St., San Francisco.

ARTESIAN WELLS WANTED.—Parties who ars prepared to contract for boring artesian wells are invited to send terms to Edward Frisbie, proprietor of ths Reading Ranch, Anderson, Shasta County, Cal.

MODEL MAKER AND MACHINIST.—I. A. Heald, No. 51½ Commercial St., San Francisco, (fourth floor.)

A FLOURING MILL is wanted at Reading, ths head of railroad transportation in Shasta County.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

Cherokee Flat Blue Gravel Company.—

Location of principal place of business, San Francisco, California. Location of works, Cherokee Flat, Butte County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 20th day of December, A. D., 1878, an assessment (No. 40) of five cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the Company, 318 Pine street, Room 6, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 28th day of January, 1879, will be delinquent, and advertised for sale at public auction; and unless payment is made before will be sold on Tuesday, the 18th day of February, 1879, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors. R. N. VAN BRUNT, Secretary.

Office, 318 Pine Street, Room 6, San Francisco California.

Land Purchaser's Association. — Office,

No. 318 Montgomery Street, San Francisco, California.

NOTICE -There are delinquent upon the following described stock, on account of assessment (installment No. 43) levied on the 5th day of November, 1878, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Certificate.	No. Shares.	Amount
Mrs Matilda Stohr.....	38	1	$4 00
James L Beyea.....	43	1	4 00
V Chevallier.....	64	1	4 00
Geo S Dickey.....	98	1	4 00
W G Koch.....	178	1	4 00
Asa Fisk.....	220	1	4 00

And in accordance with law, and an order of the Board of Directors, made on the 5th day of November, 1878, so many shares of each parcel of said stock as may be necessary, will be sold at public auction, at the office of the Secretary, No. 318 Montgomery street, San Francisco, California, on Saturday, the fourth (4th) day of January, 1879, at the hour of 10 o'clock A. M. of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of the sale.

C. S. WRIGHT, Secretary.

Mineral Fork Mining and Smelting Com-

pany.—Location of principal place of business, San Francisco, California. Location of works, Big Cottonwood District, Salt Lake County, Utah Territory.

NOTICE.—There are delinquent upon the following described stock on account of assessment (No. 1) levied on the 31st day of October, 1878, the several amounts set opposite the names of the respective shareholders, as follows:

And in accordance with law, and an order of the Board of Directors, made on the 31st day of October, 1878, so many shares of each parcel of such stock as may be necessary, will be sold at public auction at the office of the Company, Room 20, Safe Deposit Building, No. 328 Montgomery Street, San Francisco, California, on Monday, the thirtieth (30th) day of December, 1878, at the hour of 12 o'clock M. of such day, to pay delinquent assessments thereon, together with costs of advertising and expenses of the sale. OTTO METCHKE, Secretary.

Office, Room 20, Safe Deposit Building, No. 328 Montgomery St., San Francisco, California.

POSTPONEMENT.—The above sale has been postponed until Thursday, the 30th day of January, 1879, at the same hour and place. By order of the Board of Directors.

OTTO METCHKE, Secretary.

Orion Mining Company. — Location of

principal place of business, San Francisco, California. Location of works, Iowa Hill, Placer County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 12th day of December, 1878, an assessment (No. 4) of twenty-five cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the Company, No. 28 Sansome street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 13th day of January, 1879, will be delinquent, and advertised for sale at public auction; and unless payment is made before will be sold on Tuesday, the 28th day of January, 1879, to pay the delinquent assessment, together with cost of advertising and expenses of sale. By order of the Board of Directors. P. CONKLIN, Secretary.

Office, No. 28 Sansome St. (up-stairs) San Francisco, Cal.

Summit Mining Company.—Location of

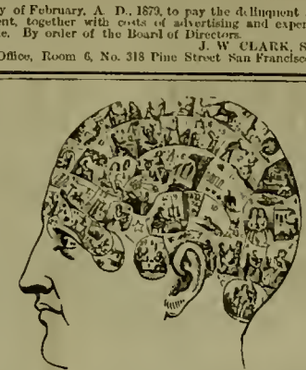
principal place of business, San Francisco, California. Location of works, Mineral Point Mining District, Plumas County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the nineteenth day of November, A. D., 1878, an assessment, (No. 6,) of five cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of said Company, 318 Pine street, San Francisco.

Any stock upon which this assessment shall remain unpaid on the sixth (6th) day of January, A. D., 1879, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on the fourth day of February, A. D., 1879, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

J. W CLARK, Sec'y.

Office, Room 6, No. 318 Pine Street San Francisco, Cal.



Barlow J. Smith, M. D.

Consulting Physician,

Professor of Phrenology and Mental Hygiene.

Proprietor of the Smithsonian Medical and Phrenological Institute, 635 California Street, above Kearny.

This Institute, by combining medical hygiene with the various Water Cure treatments and the most powerful Electrized Horseshoe Magnet in the world, claims to cure speedily and permanently all forms of acute or chronic nervo-vital derangements, Brain, Spinal and Heart diseases, St. Vitus Dance, Palsy, Epilepsy and all Rheumatic, Liver and Kidney troubles. The institution has for the past 20 years made a specialty of treating all forms of weaknesses and diseases peculiar to males and females. By the use of hygienic remedies and electro-metropathy the worst forms of impotency and seminal weakness in males and sterility in females are speedily and permanently overcome. Hygienic board, with or without rooms. Terms moderate. Electro-thermal, Russo-Turkish and Medicated Baths given daily.

Mrs. Dr. Smith as Matron has charge of the female bathing department.

DR. SMITH has practiced Phrenology the past 30 years, and during the last 20 years has been constantly using the science connected with Physiognomy, in examining or diagnosing disease in this city, and claims to have made discoveries in the SCIENCE of Phrenology that enables him, by an examination of the head, even blindfolded, to determine the disease to which the person is constitutionally subject, or whether the disease at the time afflicting the person, is the result of accident or hereditary weakness; whether CONSUMPTIVE, DYSPEPTIC, RHEUMATIC, APOPLECTIC, NEURALGIC, LEUCORRHEAL or SEMINAL. Especially does the form of the head indicate the strength of the uterine, genital or reproductive system. The head is also an index of the natural strength of the lungs, heart, stomach, liver, kidneys, spleen, back or vertebra, and it determines the power of the system in warding off and overcoming disease of all kinds.

Ladies or gentlemen, desirous of obtaining a thorough and correct Phrenological examinations with Fowler and Wells' charts, will meet with a respectful reception at his consulting rooms. Parties can depend upon a reliable delineation of the character of their intimate male or female friends, by presenting a clearly defined photograph.

Phrenological or Physiognomical examinations without charts, $1.50; with charts, from $2 to $3.

INVITATION TO INVALIDS

And all persons who are in any way out of health, who desire to know the nature and causes of their disease, may avail themselves of an examination through phrenology in regard to health free of charge, between the hours of 9 A. M. and 8 P. M. Sundays from 9 A. M. to 12 M.

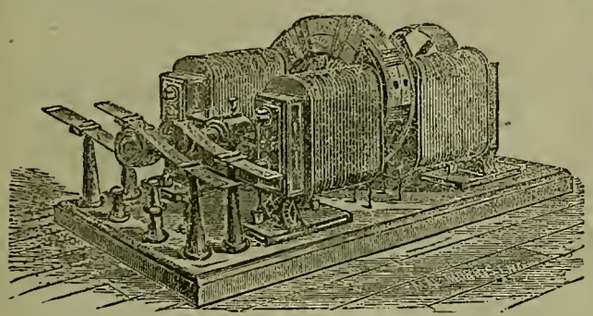
ELECTRIC LIGHT.

BRUSH PATENT.

The Best, Cheapest, Cleanest, and Most Powerful Light in the World.

In daily use at the Palace Hotel and the Union Iron Works, S. F.



For Lighting Mines, Factories, Mills, Streets, Theaters, Public Halls, Etc., It has no Equal, either for Brilliancy or Cheapness.

For further particulars, Catalogues, Prices, Etc., apply to

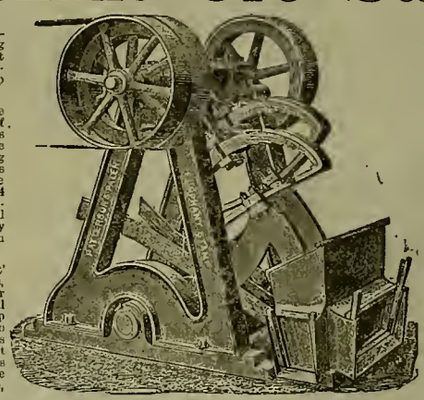
WILLIAM KERR,
President S. F. Telegraph Supply Co.,
903 Battery St., San Francisco.

Elephant Ore Stamp.

We beg to call your attention to this engraving representing the Elephant Ore Stamp. The advantages claimed for this Stamp are as follows:

Capabilities.—The "Elephant" is capable of crushing as much stuff as a 12-Stamp Battery of the present system, having crushed as high as 1½ tons of tough copper ore in one hour, through a No. 4 punched screen. The undersigned, however, will guarantee 20 tons per day of ordinary quartz through the same size screen.

Wear.—The 'Elephant' having only two pairs, Shoe and Dies, the wear in this instance is equal to one-sixth of a 12-Stamp Battery. There being no Cam Tappets, Cam Shafts or Guides, the consequent wear on these parts is done away with; the leather thoroughbrace, uniting the lever with the spring, would only require replacing at most, once a year.



Power.—The "Elephant" only requires a seven horse-power engine to drive it, where a 12-Stamp Battery would require from 18 to 20 horse-power.

Portability.—The entire Battery, including Mortar, will weigh about six tons, thereby causing an immense saving in the way of freight to such places as Arizona, Mexico, Carihoo and Bodie. As no part of the Machine weighs more than 1,800 pounds, the handling of the Machine is comparatively easy, and in places where it would be necessary to pack the Machine on mules, it could be easily made in pieces not to weigh over three hundred pounds.

The above engraving shows the Machine in exactly the position it would be placed in a mine; the reader will therefore see that all wood work is done away with, and that once the Machine is on the ground it will take but a few days to set it up and have it in full working order. The "Elephant" can be seen working every day from 2 to 4 P. M. at No. 342 Main street, near Harrison, San Francisco. For particulars apply to

EDMUND WHITE, Care of A. B. Grogan, 705 Sansome Street, San Francisco.

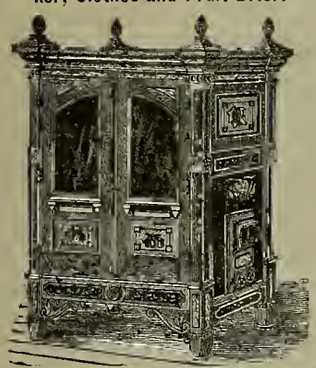
DEFLECTED HEAT!

Boswell's Combined Heater, Cooker, Baker, Clothes and Fruit Drier.



Combining the advantages of a Stove, Furnace, Oven, Dry House and Kitchen Range. An application of Scientific Principles to the economy of living, of labor, of health and of comfort. A handsome piece of Furniture adapted to the wants of every family. It equally economizes time, labor and fuel, and avoids exposure to heat in cooking as well as in baking. It bakes Bread, Cakes and Pies to any desired tint without turning or watching, or danger of burning. All odors produced in cooking are passed up the flue. Food cooked by deflected heat is improved in flavor, more easily digested, contains more nutriment, will keep fresh longer, and is also much improved in appearance. The stages of the cooking or baking can be seen without stooping or opening the doors of the oven. It will dry and bleach your clothes in from half an hour to one hour and a half, and heat your irons.

Fruit dried in the Boswell will gain from TWENTY to FORTY PER CENT. in WEIGHT, and THIRTY PER CENT. in QUALITY over that dried by any other process. It will successfully dry any kind of Fruit, Grapes, Berries, Meats, Fish, Vegetables, Coffee, Tobacco, Corn and Grain of all kinds.

— ALSO —

Boswell's Commercial Fruit Drier,

Used exclusively for drying and heating purposes ON A LARGE SCALE.

— ALSO —

BOSWELL'S CABINET HEATER,

Of all sizes and capacity for heating Private Residences, Hotels, Halls, School Houses, Churches, Offices, Stores, Railroad Cars, Hospitals, etc.

All of which can be operated successfully by a mere child, it is so simple in its construction, and with one-third the usual amount of fuel (coal or wood), used in any other heating, cooking or drying apparatus.

Every farmer and economical housekeeper should use it. It will pay for itself in the saving of fuel; it will pay in the superior character of its FRUIT DRYING, of its COOKING, ROASTING and BAKING; it will pay in its salubrious and healthful warm air; it will pay the rich and the poor alike.

Address, for Price List and descriptive illustrated circulars,

Boswell Pure Air Heater Co.,

Pocket Map of California and Nevada.

Compiled from the latest authentic sources, by Chas. Drayton Gibbs, C. E. This map comprises information obtained from the U. S. Coast and Land, Whitney's State Geological, and Railroad Surveys; and from the results of explorations made by R. S. Williamson, U. S. A., Henry Degroot, C. D. Gibbs and others. The scale is 18 miles to 1 inch. It gives the Judicial and U. S. Land Districts. It distinguishes the Townships and their subdivisions; the County Seats; The Military Posts; the Railroads built and proposed, and the limits of some of them; the occurrence of gold, silver, copper, quicksilver, tin, coal and oil. It has a section showing the heights of the principal mountains. The boundaries are clear and unmistakable, and the print good. 1878. Sold by DEWEY & CO. Price, postpaid, $2; to subscribers of this journal, until further notice, $1.

Take the Paper that stands by your Interests.

VOLUME XXXVIII Number 2.

Walled Lakes.

During the explorations this season of Prof. Hayden's parties in the Yellowstone National park, many mountain lakes were found to exist, besids Yellowstone lake, the largest and best known among them all. They are beautiful sheets of water, and surrounded as they are by the quiet grandeur of the mountain scenery, their loveliness is very impressive. When one has gratified himself with admiration of their picturesque beauty, and comes to give them more detailed examination, he discovers among their interesting features—the existence upon their shores of those peculiar embankments which have been called "walls." These are especially observable upon the shores of Heart lake, one of the tributaries of Snake river, and in one of Mr. Jackson's fine photographic views of that lake the wall is clearly shown.

The position of these embankments is upon the gently sloping shores, and at or near the high water level, which at the time of low water is often some rods from the margin. Similar embankments exist upon the shores of the numerous small lakes of northern Iowa and southern Minnesota, and in other northern States, and their origin was the subject of much vague speculation, until a few years ago, when it was clearly explained by Dr. C. A. White, in his report on the geology of Iowa, as follows:

"The water is usually lowest in late autumn, and when winter comes it is frozen to the bottom over a wide margin from the shore. The ice, of course, freezes fast to everything upon the bottom, whether boulders, sand, gravel or mud, and the expansive power of the water in the act of freezing is exerted upon them, acting from the center of the lake in all directions towards its circumference. Those who are familiar with the expansive power of ice in the act of forming, will readily see that under such circumstances it would be more than sufficient to move the largest boulder up the gentle slope of the bed of the lake. It is true that the motion resulting from one winter's freezing would be hardly perceptible, but the act repeated from year to year, and from century to century, would ultimately move everything upon the bottom beyond the reach of the ice. The tracks of boulders thus moved have been observed, being as unmistakable in their character as those which the river mussel leaves behind it in the sand.

"Thus it will be seen that whatever was originally upon the bottom of the lake, within the reach of the ice, whether boulders, sand, gravel or mud, has been constantly carried towards the shore, where we find them collected in perfectly natural disorder, and forming a ridge just where the expansive power of the ice ceased. Below the line of freezing, the same kind of material would of course remain unmoved upon the bottom, because there is nothing to disturb it.

"The embankments vary in hight from 2 to 10 feet, and from 5 to 20 or 30 feet across the top, their size and outline varying according to the materials which compose them. If boulders were numerous upon the bottom, the adjacent embankment is largely composed of them; if sand prevailed, a broad, gently rounded embankment resulted, just such as might be expected from that material; and if mud, filled with the fibrous roots of water plants and sedges were brought out by ice, a steep, narrow embankment was formed, because such material will stand more erect in a ridge or embankment than sand or boulders will.

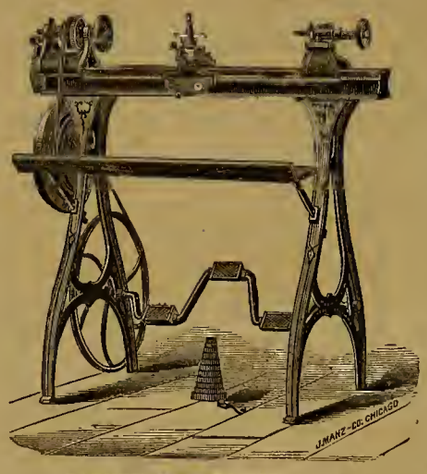
"This description was applied especially to the so-called walled lakes of northern Iowa and southern Minnesota, the embankments of which were formally believed by many to have been of artificial origin, but it applies equally well to the mountain lakes of the Yellowstone National park."

THE third-class ore from the White & Shiloh Con., Battle Mountain, Nevada, produces crude bullion that goes from $11,000 to $12,000 per ton. The first and second class ores are shipped.

Barnes' Foot-Power Lathe.

Messrs. Osborn & Alexander, of 628 Market street, in this city, dealers in hardware, lathes, scroll saws, etc., are also agents for Barnes' improved lathe, which is illustrated on this page. This No. 5 lathe is a strong and powerful engine lathe, having all the necessary appliances for rapid and accurate execution of heavy or light work. The size will best accomodate the requirements of those wishing a lathe for general work within the range of foot work, for manufacturing or repairing purposes. It is substantially built of iron, steel and brass, each used where they will best serve. Every part is in true proportion and all arranged for convenience, strength and durability.

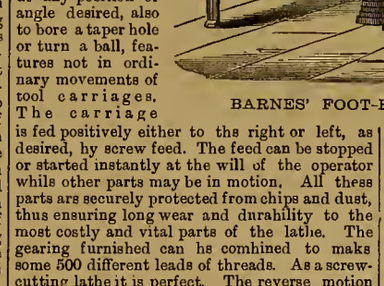
The tail stock can be instantly set at any desired point, or taken altogether from the lathe bed and without wrench or removing bolts. It can also be set over for turning tapers. The spindles of both head and tail stock are of cast steel with positively true taper holes for the reception of the centers. The center of the tail stock is self-discharging.



BARNES' FOOT-POWER LATHE.

The tool carriage is a model of convenience and accuracy. The tool can be set to the work at any position or angle desired, also to bore a taper hole or turn a ball, features not in ordinary movements of tool carriages. The carriage is fed positively either to the right or left, as desired, by screw feed. The feed can be stopped or started instantly at the will of the operator while other parts may be in motion. All these parts are securely protected from chips and dust, thus ensuring long wear and durability to the most costly and vital parts of the lathe. The gearing furnished can be combined to make some 500 different leads of threads. As a screw-cutting lathe it is perfect. The reverse motion used renders it practically impossible for the tool to change its cut when being returned.

The are *no cast gears* used in the gearing of this lathe. All the gear wheels are cut in the best machinery known for gear cutting, from solid metal and are positively true and as noiseless as it is possible for metal gear. This lathe weighs 225 lbs., and except the balance wheel of 30 lbs. the weight is all in its working parts, which is a great consideration when compared with the lathes arranged with the old faulty foot-power motions, the balance wheels of which often weigh 200 lbs., or more than all the balance of the lathe. This great weight is entirely useless except to overcome faults in a defective foot motion.



ELTERICH'S SCREW CUTTING TOOLS.

Angular belting is used on this as well as on other lathes, from the fact that it will drive stronger and never casts from the cones. This lathe with its back gearing and differential pulleys has a greator range of speeds than has ever been before offered in a foot-power lathe for the price. The seat hinges at one end, allowing the operator to pass between it and lathe to be seated. The price of the lathe is $115, a lower figure than for other lathes, and all necessary wrenches and belting with face plate and centers are furnished.

Machine-Shop Rambles.

Edwards' Western Iron Works.

We have lately visited the works of Perry Edwards, 316 and 318 Mission street, and learned much there that is of general interest. At these works a specialty is made of what may be termed the fine art of iron work. All have noticed and admired the artistic iron fencing that surrounds many of our most attractive residences. The crestings upon the roofs of our houses are none the less attractive, and display in many cases great ingenuity and taste in plan and execution.

There is another style of work which, if, not artistic, makes upon the mind a stronger impression than does that which is truly beautiful: we speak of the iron work about prisons; the ominous gratings, the heavy bolts and bars and doors. It is work of this class that is done at the Western Iron Works. Mr. Edwards has just finished an order for 250 feet of

Iron Fencing

For parties in Napa. Most of his work in this line is for orders out of the city. He has on hand now a job of 400 feet of fencing and cresting. He furnished the new Hall of Records with iron doors and shutters, and has lately finished a large iron

Hot-Air Drier

For the Magdalen Asylum. This drier is 16 feet long, 12 feet wide and 3 feet high. A fire is built under it. The air circulates through the drier, becoming heated and passing off up the chimney. The clothes are hung above the drier after washing.

Perhaps the most interesting department of his work is

Model-making.

In this line the most notable job that he has lately done is the making of the iron work for Russell's amalgamator. This machine has acquired some little notoriety as being the pattern used at the ocean placers, which a few months ago attracted so much attention.

In addition to the classes of work we have mentioned, Mr. Edwards advertises to do all kinds of house iron-work, including the manufacture of wrought-iron girders, trusses, nickle-plated railings, and bank and store fittings.

PACIFIC COAST POSTAL CHANGES.—The following are the changes for the week ending Jan. 4th: Offices Established—Little Stony, Colusa county, California; James R. Davis, Postmaster. Home, Baker county, Oregon; Wm. S. Glenn, Postmaster. Greaterville, Pima county, Arizona; Thos. Steele, Postmaster. Grouse Creek, Box Elder county, Utah; Mrs. S. H. Kimball, Postmistress. Postmasters Appointed—Hiram Lush, Jacob City, Tooele county, Utah; R. O. Shirley, Logan, Cache county, Utah.

THE Ruby Hill (Nevada) *Mining Report* urges the erection, by some well-disposed capitalist, of a $5,000 sampling works for the accommodation of that district.

Three More Railroads.

The signs of the times have shifted. Let us see what we see:

In Arizona it is evident that they are building the Southern Pacific railroad from the West End. It is well known also that both the Denver & Rio Grande and the Atchison, Topeka & Pacific Railroad Companies, which have been building energetically southwestward, have, both of them, vitality enough to reach the western boundary of New Mexico in due time. The connecting route is the present freight route from the East to Tucson. It will continue to be such only a very short time, for San Francisco will tap the Tucson trade and will have all of it, until the Eastern people reach out for it, just as we are doing, with an iron road.

The Northern Pacific people have let contracts for building a section that will bring them up speedily to the Rocky mountains from the east end. The great wheat plains of eastern Washington, which shipped the past year more than their million bushels of wheat, are well known to be rapidly extending their plowed acreage, but the country has no railroad. The Northern Pacific survey runs through those wheat fields for several hundred miles. Does anyone imagine that the Northern Pacific Railroad Company is so dead, at the present time, as not to be able to build that part of their road under such conditions? If so, he will probably live to learn that a portion of the grain crop for the present year, and all of it for the next in the upper Columbia country, will be moved by the Northern Pacific railroad. The route surveyed last season, between the Upper Columbia and the Wilkeson branch to the Mt. Rainier coal region, was found satisfactory; and that connection will be made as the next step, taking the statement of Superintendent Black as our evidence of the intentions of the company.

It is not generally known nor understood that the Canadian Pacific railway is in progress of construction at Winnipeg, and that the Canadian ministry have procured a large loan in England, the object of which is understood to be the building of the railway. Every foot of the line has been located by location survey on a most advantageous route, after surveying some 30,000 more miles on other lines, for making comparisons of routes and getting the best. The Canadian Premier, Sir John McDonald, represents the city of Victoria, and the policy of beginning construction immediately at the western end and carrying it on simultaneously with construction at the eastern end.

Screw Cutting Tools in Sets.

At Dunham & Carrigan's hardware store, in this city, they have a variety of improved screw cutting tools in sets, all packed in neat boxes ready for use. A representation of a set of Elterich's tools is shown on this page, showing a No. 3 set, in walnut box. No. 1 contains one die-holder, one tap wrench, and one tap and die each. Nos. 4, 6, 8, 10, 16 and 14, price in walnut case, $7. No. 3 (shown in the cut), contains a die-holder, tap wrench, and one tap and die each of Nos, 2, 3, 4, 5, 6, 8, 12 and 14, and two each of No. 10 taps and dies. Price in walnut case, $10.

These are furnished with standard machine-screw threads and plug taps. The dies cut rapidly, and furnish a perfect thread at one cut. They are made exact to size, but can be adjusted for wear. The taps are hand-made, ground out and relieved, so that they can be hacked out from the work without breaking. Every tap and die is warranted. The sets are put up in neat boxes, and are all good serviceable tools, well made and neat in appearance.

SPECIAL CORRESPONDENT, Capt. Wm. H. Seamans, of Oakland, left for Prescott, Arizona, on Tuesday of this week. He will visit some of the northern and other mining districts of the Territory on private business, and has promised to take notes and send some letters to the PRESS from such places as are not visited by our general agent and correspondent.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

The Search for Refractory Ores.

Editors Press:—Let us understand each other. What do we mean by "refractory ores?" I am aware that, by miners, the term is applied, as regards gold, to all such as cannot he satisfactorily treated by simple amalgamation in batteries and on plates; as regards silver, to such as cannot he worked raw in iron pans. Those ores which are made profitable by these simple means are denominated "free milling," even though, as at Virginia, there may be a considerable loss of precious metal. Among metallurgists, however, I opine that refractory ores are those which present considerable difficulty in their treatment hy any generally known process, for of secret processes no account can he taken. Refractory ores which defy the metallurgist then, are those which, though containing enough metal to pay the cost of the intelligent application of known methods of extraction, cannot be worked satisfactorily because of the failure of such methods to extract the metal.

A metallurgical success necessarily involves the element of profit; for metallurgy is a science applied to the wants of life, and an operation which is conducted at a loss, however satisfactory in a purely scientific point of view, cannot be called a metallurgical success in any practical sense.

On the other hand, however, the mere fact that a profit is made does not of itself justify the claim of a metallurgical success; for this, to my thinking, requires that the given ore shall he worked as closely as is possible by known means, consistently with the greatsst profit, which again does not always mean the largest immediate return; for since mines are not inexhaustible, practically, economy of ore is to be considered. Thus I have never been able to consider the work done on the Comstock as a metallurgical success, because I have had reason to think that hetter work might bave heen done, with greater profit to owners; and so with the gold quartz milling, though often profitable, it cannot be called metallurgically successful if 30% of the gold is lost as some say; unless, indeed, the resources of science are inadequate to the saving of a higher percentage, with equal or greater profit. I know of a large copper mine which is said to yield a profit, though only about half the copper is extracted. This is not a metallurgical success, because, by the use of a better process, almost all the copper can he got, with increased profit.

Poor ores which do not contain sufficient metal to pay the cost of manipulation, under the couditions of locality, etc., are not necessarily refractory.

To sum up, refractory ores are those which are difficult to work; and refractory ores which defy the metallurgist, are those which cannot be worked. Poor ores, whether refractory or not, must await the increase of facilities, and improvement of machines and processes.

Ores which can he worked by the O'Harra furnace are not refractory, for that furnace is nothing more nor less than a reverheratory furnace, with automatic stirring apparatus, and any ore which can be worked in it cau he worked in tbe old reverberatory; the difference is in the cost, so that the ore, previous to the introduction of the O'Harra furnace, was in the category of *poor ores*, from which that furnace has redeemed it.

With the Willard furnaco the case is somewhat different. It involves priuciples whicb, though not new, have not, I think, heretofore been so well applied. It presents two advantages: firstly, avoidance of dusting; secondly, a low temperature. Perhaps, I may add, a better olimination of arsenic and antimony, etc. Its performance will be watched with interest.

I have heard a great deal about the Meadow Lake ore, aud intend to inform myself further about it. In the meantime I will observe that there are two classes of men who are very liable to fail in treating ores. Ono is the theoretical, laboratory man, who knows nothing of practical work or husiness, and is led away hy scientific zeal. He may make a chemical success, but is apt to fail in the pecuniary point. The other is the self-styled, self-sufficient "practical man," who, having picked up, without having comprehended, the routine of operations in one place, finds himself, under new conditions, utterly helpless; unable to succeed in any sense and equally unable to give an intelligent reason for failure.

If the owners of ores which are thought to be refractory will come forward with a few facts, some among us may be enabled to assist them with mutual bensfit. In order to elicit this information I will take the liberty of asking these gentlemen a few questions:

1. What aro the valuable contents of your ore, kind aud quantity per ton?
2. What is the price of fuel, labor, lumber and freight from point of supply; or where ie the miue?
3. What methods bave been tried, and with what results?
4. What is the matter with your ore? Why is it refractory? What makes it so?

With the answers to these questions hefore us we can think intelligently about it, and if light appears to some one of us, a sample of the ore can he sent for and experimented on.

I will conclude with a proposition upon which I have heretofore enlarged in your columns. Any chemical operation which succeeds on a small scale, will gives the same result on a large scale, if all neccssary conditions are maiutained. It is only hy a rigid regard of this rule that metallurgical experiments on a small scale can he relied on. Any ore which can hs worked with profit on a small scale can he worked with more profit on a large scale, if the supply of material to work on, and to work with, is adequate. C. H. Aaron.

Defects in the Mining Laws.

Editors Press:—Having noticed an extract from your paper, pnhlished in the *Miner* here, I am induced to say something further. The article had relation to the U. S. mining laws of 1866 and 1872. I think we feel the injustice here, probahly more than any other State does, of these acts. They doubtless were framed by men who knew nothing ahout a mine, or what the miner needed to protect him from fraud and robbery. Your remarks are true, here, "that the miner himself enacted local laws which were far hetter suited to his requirements than any law yet passed by Congress or Legislature." The trouhle is we send politicians to represent us who know nothing of, and care less for, the interest of the miner.

This State perhaps is peculiarly situated, differing from any other mining State in its formation. Our veins or lodes (which we call lodes), will average probably one for every acre of surface in a mining camp, say 10 miles square. Of course niue-tenths of these are nothing hut feeders and spurs from the main vein. Hence, in nine cases out of 10, locations and discoveries are made on these spurs, and the main fissure vein is liable to be left undiscovered, as generally in this country the main vein is deeply huried in the drift or slide.

These locations (utterly worthless except as occupying the ground to prevent the prospector from coming anywhere in the neighborhood), he holds ou speculation to sell. It is for the public interest that the fullest latitude should be given to the prospector, for to him alone is the public indebted. There is one instance in this county where flow of the richest quartz, worth from $1,000 up to $10,000 per ton is found, but the lode has not yet heen found, and probahly will not for years to come, as all the ground is taken up by these worthless discoveries, which in many cases are held by patents. The prospector is warned off and is considered a trespasser; hence he seeks other fields for exploration.

Another objectionable feature we find in the law here. For instance, A makes a prior location of 1,500 feet in length by 150 feet in width, (as our local law is here). B makes a subsequent location and crosses A's claim at a point so as to take in A's discovery or location. B makes application for his patent for 1,500 feet long and 150 feet wide, and, hy the terms of the law, A must lose not only the strip across him 150 feet wide which B is claiming, but his whole claim 1,500 feet long, unless he adverses B at the land office, and show the facts in the case. What harm has A done that he must pay from $200 to $500 to prosecute this adverse suit?

I could continue to cite many more objections to this law of 1872. It is very true, I think as you intimate, that the men who made this law knew nothing of what they were legislating about. The member from Mississippi I guess was about right. We eend men from these mining States, not for what they kuow of our interests, but for the amouut of money they can command to purchase votee at the election, no other qualification is requisite.

This State's richness in mines is but beginning to be known, we have had to learn everything hy practical experience. If Congress can let us alone Colorado will soon prove to the world that she stands second to none of her mining sisters. Yours respectfully, S.

Georgetown, Colorado, Dec. 22d.

Cost of Artesian Wells.

Editors Press:—I see in a late number of the Press an article giving the cost of artesian wells. It seems too higb. The regular price in this county is as follows: Boring first 100 feet, $50; each additional 50 feet, 50 cents per foot more. Pipe, No. 14 sheet iron, joiuts two feet long and lapping half way, 85 cents each; No. 16 iron, 70 ceuts each; diametor, seven inches. A larger diameter would cost more, but not a great deal. The strata commonly met with are: Quicksand, blue clay, black clay, cement, gravel, boulders, etc., alternating; no hedrock.

The farmer or person on whose land the well is bored, boarde the hands that bore the well, and generally moves the tools from the last well to his place. Wells in this county are of all depths, from 70 feet to 400 feet, and flow from oue inch to seven inches over the top of the pipe, and sometimes more. Well Borer.

Westminster, Los Angeles Co., Dec. 24th.

Refractory Ores.

Editors Press:—I see pnblished in your columns an inquiry from C. H. A., asking where to find refractory ores. I have several lodes containing gold, silver and copper—no lead. The assays run from $10 to $600 in gold, from $14 to $400 in silver, aud from 10% to 60% in copper. The mines are situated at Caribon, Oneida county, Idaho, not far from Soda Springs. The hest route is by way of Corinne, Utah. If anyone who wishes to inspect the mines will come ahout the first of May, I will accompany him to ths mines. I have men at work there all winter. None of the mines are well developed. The most fully developed so far is the Oneida. They are down 80 feet on this mine. The assay is $720 to the ton, all gold. As yet no capital has taken hold.

There are good placer mines in the vicinity, about 15 miles from Snake river. The miners are all doing well. The formation is granite and porphyry. The gold is fine flour. The dirt seems to pay very evenly from top to hottom. There is plenty of wood and water.

Anyone can see samples of the different ores by calling on me at Corinne, Utah. The distance from this place to the mines is ahout 140 miles. Part of the way may he traveled hy rail. It is possible to go from here by teams in five days. Hiram House.

Corinne, Utah, Dec. 24th.

[Mr. Honse does not say whether the ore can be worked or not. It would he well for him to eend us some account of any attempts that have been made at working the ores; also more complete analyses of the same.—Editors Press.]

Snake River Again.

"Forty-niner," writing again to the Salt Lako *Tribune*, joins issue with "Snake Bite" on the gold-washing question.

I say again, place tbe boxes coutaining the plates, as flat as you can, and have the sand wash off, aud not clay the plates. I take issue directly with the Biter'e idea that the "finer the gold the steeper the plates should be set." It will not staud the test of practice or experience, and I have had over 20 years of both, in saving gold, from the old arastras up to the latest styles of batteries, plates and pans.

The slower the gold can be made to pass over the plates, the more will adhere to them. A single trial of five minutes in front of hatteries mining rich rock, will convince anyone of this, holding a plate at different degrees of pitch so that the pnlp passee over it.

If they are too steep, or too mucb water, when a swift current passes over them, much of the gold goes also. This is too well known to need argument with those who are posted. I now quote the crooked one: "1st. It is not neccssary in the new machine to fork out the coarse rock, as he states; it would cost too much." I did not state anything of the kind. I said it must he doue. If this labor can be avoided by placing perforated iron plates over the amalgamated platcs, and have everything carried over but fine sand and gold, I have no objection, only that it will he more expensive in the outfit, and some saud and gold will pass with the coarse material.

I now add to the directions given hefore: If there is tough clay or other material holding and mixed with the gold, which requires a good head of water and swift motion, spread the last sluice out like a pan or table, and divide the current of water with cleats and stops, so that the water and sand spread out evenly and wash slowly over the plates.

I will say for the process stated of amalgamating the plates that it has given good results for 25 or 30 years on the coast. I have used platee so amalgamated until they were worn out and replaced by new ones, the old ones being sold for $1 per pound, and melted for the gold they contained. On plates inside of the batteries, the amalgam will sometimes get very thick and hard, and adhere so firmly that it has to be chipped off with a chisel, and on the same plate perhaps (where violent splashing occurred) there would he spots where the amalgam was washed off through to the copper. But outside of the batteries where the plates can be seen, and a little quicksilver applied when such spots appear, no difficulty will occur in keeping them amalgamated.

As before stated, on the bowl of quicksilver used for this purpose, keep a solution of cyanide of potash. Some millmen assert that the weak eolution of acid is no henefit, others as stoutly insist that it is. I always found the quicksilver more effective in the pans when it was used. Try both and use your own judgment. This is anyhody's process, and has stood the test of long years of practice with practical amalgamators.

Our Solar System.—Exclusive of comets, there are now 224 members of our solar system known. There are now 190 asteroids known, unless others have been discovered since October 1st. In 1875 there were 17 discovered, the greatest number in one year. Prof. C. H. F. Peters, of the Litchfield observatory, Hamilton college, has discovered the greatest number, 31. Prof. Watson followe him in the list, having discovered 23.

Why the Sierra Nevada is Larger than the Coast Range.

A Legend of the Yokuts.

Stepheu Powers, in his "Indian Tribes of California," relates occasional legends of the strange peoples he visited. Many of these traditions are in themselves silly, child's fables, hut viewed from the standpoint of ethnology they possess peculiar interest. The tribe of tho Yokuts lived, or rather their remnants still live, ahout the northern half of Tulare lake, reaching as far north as the hend to the eastward of the San Joaquin, and extsnding to the east and west as far as the Sierras and the Coast Range respectively. The following legend belongs to this tribe. Powers entitled it the

Origin of the Mountains.

Once there was a time when there was nothing in the world hut water. About the place where Tulare lake is now there was a pole standing far up out of the water, and on this pole perched a hawk and a crow. First one of them would sit on the pole awhile, then the other would knock him off and sit on it himself. Thus they sat on top of the pole above the waters for many ages. At length they wearied of the lonesomeness and they created the birds which prey on fish, such as the kingfisher, eagle, pelican, and others. Among them was a very small duck, which dived down to the hottom of the water, picked its heak full of mud, came up, died, and lay floating on tho water. The hawk and the crow then fell to work and gathered from the duck's beak the earth which it had brought up, and commenced making the mountaius. They commenced at the place now known as Ta-hi-cha-pa pass, and the hawk made the east range, while the crow mado the west one. Little hy little, as they dropped iu the earth, these great mountains grew athwart the face of the waters, pushing north. It was a work of mauy years, hut finally they met together at Mount Shasta, and their lahors were ended. But, behold, when they compared their mountains, it was found that the crow'e was a great deal the larger. Then the hawk said to the crow: "How did this happen, you rascal? I warrant you have been etealing some of the earth from my hill, and that is why your mountains are the higgest." It was a fact, and the crow laughed in his claws. Then the hawk went and got some Indian tobacco and chewed it, and it made him exceedingly wise. So he took hold of the mountains and turned them round in a circle, putting his range in place of the crow's; and that is why the Sierra Nevada is larger than the Coast Range.

This legend is of value, says Powers, as showing the aboriginal notions of geography. In explaining the story, the Indiau drew in the sand a long ellipse, representing quite accurately, the shape of the two ranges; and he had never traveled away from King's river,

Further, it may he added, this legend and all of similar origin, are of valuo in correcting the ideas of "city folks" with regard to the California Indians. Those who have seen only the "Digger" in his debauched indolence, as he hange about some etage station, have no right to form an opinion, based upon tbeir own experience, of those unfortunate people. They do not deserve the approhrium attached to the term "Digger." They are interesting tribes, that have a history. They are falling hefore the advance of a people far better than themselves; hut not so much better, that the uncivilized cannot point to the civilized as the hasteners of the Indian's destruction. "We shall all die soon," wails the Yokuts Indian in his dance for the dead. "We were a great people once. We are weak and little now. Be sorrowful in your hearts. O, let sorrow melt your hearts. Let your tears flow fast. We are all one people. We are all friends. All our hearts are one heart."

Buying Gold at Boise.

Gold bullion is now purchased at the United States Assay office at Boise, Idaho, and paid for at its coining value in U. S legal tender notes at par, subject to the following deductions:

1. One-tenth of one per cent. for melting and assaying, with a minimum charge of ten cents for auy deposit of less value than $100.
2. When the character of the hullion is such as to require toughening, a charge for that operation will be made of from one half to two ccnts per ounce gross, according to the condition of the deposit, and on any such deposit of less weight than five onnces the charge will be imposed as if the weight was five ounces.
3. A deduction will he made from each purchass at the rate of $10 per $1,000, to pay for the cost of expressage to the mint at San Francisco.
4. When the bullion contains silver to the amount of 50 cents over and above the expense of parting it from the gold, a charge of eight cents per ounce gross will he deducted, and the balance of the silver paid for at the rate of 97 cents per standard ounce (900 fine), but if after deducting the partiug charge, less than 50 cents remain, no allowauce will he made for it to the depositor. When partable bullion coutains over 100 hase metal, an additional parting chargo of one cent per ounce gross will be imposed.

MECHANICAL PROGRESS.

Dry Graphite for Steam Cylinders.

Mr. W. J. Williams, a prominent engineer of Philadelphia, has called attention to the successful use of dry pulverized graphite for lubricating steam-cylinders. He applies 137 grains twice a day, introducing it into the cylinder through the usual form of tallow-cup. Six months of continuous use, in a horizontal engine, working to its full capacity, proves this lubricant superior in every way to oils or tallow, both of which he had used for years. No oil whatever is introduced with the graphite. Besides satisfying all the lubricating needs of the cylinder, the joints, where gum is used, last longer and show less of leakage.

After a run of four months, Mr. W. says: "I took off the cylinder-head of my engine to examine the interior. I found the piston perfectly clean, with no appearance of wear or abrasion, on account of plumbago being used as the lubricator. I feel very positive that if I had been using animal or vegetable oils, the parts would be in a much worse condition today. The cylinder has been scored for several years. It is in no better or worse condition now than it was before I quit using oils (about 14 months.) The working part of the cylinder is everywhere covered with a coat of plumbago, readily soiling the fingers.

"I touched the cylinder in the same place three times, cleaning the fingers previous to each touch, but they were soiled each time.

"The conclusion I have come to about the choking up of passages is, that plumbago alone will not do it; but wherever there is friction of one or more moving parts, some of it will adhere to them.

"I have never heard a noise in the cylinder since I have been using plumbago, except when the steam is entirely shut off at the stop-valve for the purpose of stopping the engine; and then it would be heard during one or two strokes of the piston before the engine would stop, and this not oftener than usually occurs when using any kind of lubricator.

"I increase the quantity of plumbago sometimes to 180 grains twice a day; 134 is the minimum and usual quantity."

Locomotives Without Fire.

Machines on the above-named principle are now at work on the tramway from Rueil to Marly, near Paris, and with satisfactory results. The system in use is one introduced by M. Francy, an engineer, and is based on the fact that water boils at a lower temperature proportionately to the reduction of the atmospheric pressure. It is well known that water requires a temperature of 212° Fahr. to boil at the sea level; but at a higher altitude, or where the atmospheric pressure is reduced artificially, as in a partial vacuum, it boils and produces steam at a much lower temperature.

Acting upon this principle, M. Francy takes a reservoir of thin steel, we cannot call it a boiler, for it has neither fireplace nor fire, and introduces water at a temperature of 200° Fahr., and then covers up hermetically. The steam it gives off at once fills the superincumbent space, and produces a pressure of 15 atmospheres. As soon as any of the vapor is turned on for moving the machine the pressure is reduced, and the water then begins to boil, producing a fresh supply of steam. Of course that process is but of limited extent, as, at the commencement, the liquid only contained a certain amount of heat, which is gradually diminished as the reproduction of steam takes place at lower temperature by the exhaustion of the superincumbent pressure. So far a machine of this description would be obviously totally inadequate to any prolonged journey. But for short transits it has been found extremely serviceable. As the amount of pressure required to work the engine is only five atmospheres, a series of valves are so arranged as to prevent a greater amount of force issuing from the reservoir than is necessary, and thus retaining as far as possible the heat originally contained in the water. The driving part of the machinery is nearly identical with that of ordinary locomotives, with a few modifications, with the purpose of guarding against the useless waste of the heat originally introduced into the reservoir.—*Galignani's Messenger.*

A MAGIC CAR.—Mr. Blackburn, of 14 Victoria Road, Kensington, has invented a remarkable vehicle, which requires no horse to draw it. The body is in the form of a dog-cart, and the arrangement of wheels like a tricycle. The motive power, concealed in the body of the vehicle, is obtained by the combustion of benzoline, a small jet of which is admitted into a burner about the size of an ordinary chimney-pot hat. The steam passes into the cylinders of a small torpedo engine, which rotates a horizontal shaft. There is no steam given off, for it is recondensed and passes back into the tubular boiler. The weight of the steam power is about 180 lbs. On lighting the benzoline the steam requires no attention from the driver during a ride of many hours. The driver, by applying his foot to a pedal, can regulate the speed and power of draft. It travels at the rate of about eight miles an hour, and is easily directed in its course.

The Age of Steel.

By the various cheapening processes which have of late years been introduced into the manufacture of steel, that article is fast supplanting the use of iron in the various industries, and notably so for railroad purposes. Bessemer steel rails are now produced nearly as cheap as iron. It now appears to be only a matter of time, and short at that, when Bessemer and Seimens-Martin steel will be so cheap that they will take the place of wrought-iron for almost every purpose. The latest new proposed use of steel is for tin plate makers, who, it is said, are about to abandon iron for that purpose.

The Bessemer steel trade, which had its origin in England rather more than 20 years ago, still continues to be followed more largely in that country than any other. Of about 2,000,0000 tons of Bessemer steel now annually produced throughout the world, England furnishes 750,000 tons; the United States, 525,000 tons; France, 261,874 tons; and Germany, 242,-251 tons. No industry in modern times has sprung up so suddenly into importance, nor has any other caused greater changes in the way of setting aside an old and introducing a new order. To this industry in supplanting the use of iron is due the fact that thousands of furnaces have been closed up and tens of thousands of workingmen either thrown idle or transferred to other occupations. The age of iron has become the age of steel. A new departure, long threatened and greatly feared, has been actually accomplished.

Composition of Bronze for Machinery.

Much industry and research has of late been bestowed in determining what mixture of bronzes is best suited for the various portions of machinery, and to meet the requirements of each special case and purpose. We give the following as the composition of alloys approved of and used by prominent French mechanics:

	Copper.	Tin.	Zinc.
FRENCH MARINE.			
Tough bronze for rods, valves, cocks, etc.	88	12	2
Very tough bronze for eccentric straps, etc.	90	10	2
Bronze for plummer blocks	86	14	2
Hard bronze	84	16	2
Very hard bronze for shcave brass cocks	82	18	2
Bell bronze	78	22	0
Anti-friction bronze (with eight parts antimony)	4	96	0
FRENCH RAILROADS.			
Car pillows	82	18	2
Locomotive and tender oil boxes	84	16	2
" slide valves	82	18	2
Cocks	88	12	2

The bronze composed of 86 copper, 14 tin and 2 zinc is least porous, and therefore is most suitable when pressure is to be resisted.

THE IRON AND STEEL PRODUCT OF THE WORLD.—A French statistician has furnished an estimate of the world's iron product, which shows that in 1876 the whole amount footed up at 15,785,730 tons of 2,000 pounds. The coal mined is about 20 times the weight of pig iron produced. The ratio of production in the leading iron-producing countries is nearly as follows: Great Britain, 46½; United States, 17; Germany, 5½; France, 10 1-5; Belgium, 3 2-5; Russia, 3; Austro-Hungary, 2 4-5; Sweden, 2½. The iron product of the United States for 1876 was 2,690,556 tons, or about 125 pounds for every inhabitant. The estimate gives the total product of all countries of Bessemer steel for 1876 at 2,323,436 tons, of which one-fourth was made in the United States, a little over one-third in Great Britain, not quite one-fifth in Germany, and one-tenth in France. The total steel made in 1876 would lay 22,116 miles of railway track, allowing 20 pounds to the foot of rail. The present rate of production would put steel rails upon all the railways in the world in less than 10 years.

PRESERVATION OF TIMBER FOR MINING AND RAILROAD PURPOSES.—It is remarkable that so little has been done in this country with the view of preserving timber, particularly for use in mines and for railroad purposes. The matter is certainly one of great importance, and has an important bearing upon the expenditure of enormous sums of money every year, both in railroad construction and repairing and in mines. A very elaborate series of experiments upon the effect of various preservatives has recently been made in France, the result of which we hope soon to give. These experiments have been made with particular reference to preserving timber to resist the heat and dampness of deep mines.

A NEW composition of iron and steel is described in the *Revue Industrielle*. A cast-iron mold is divided into two sections by means of a transverse plate of thin sheet iron. The two metals are then poured into the respective compartments. The sheet-iron partition prevents the mixture of the metals and facilitates the welding by itself being brought into a state of fusion. It is said that the product is well adapted for safes, and that it resists drills.

WEAVING slag wool is spoken of by an English paper as a thing accomplished in that country by Messrs. Jones, Dale & Co. Strips and sheets are made of it which, it is claimed, do very well for wrapping steam pipes.

EIGHTY-TWO hundred feet of track were laid on the Southern Pacific railroad in Arizona, January 3d.

SCIENTIFIC PROGRESS.

The Alleged Dissociation of the Elements.

We made some reference, in our issue of December 28th, to the reported discovery by Prof. Lockyer that at least some of the bodies known as elements are in reality compound bodies. The announcement was made by the Professor in the following words: "Reasoning from analogies furnished by the behaviors of known compounds, I have discovered, that, independently of calcium, many other bodies, hitherto considered elements, are also compound bodies."

In alluding to this alleged discovery, a London paper, *Iron*, evidently well informed in regard to the character of Mr. Lockyer's investigations, and the general subject matter, says that it is perfectly easy to form a plausible *spectroscopic theory* to the effect that complex spectra are really built up of simpler spectra, and that *therefore* the elements giving complex spectra are probably built up of the elements giving the simpler ones. Moreover, the atomic weights can be so treated as to corroborate this view. Considerations of this kind might easily give rise to the idea of the dissociation of the elements; of the transmutation of one into another, especially within certain groups of related elements. Such, for instance, as calcium, strontium and barium; lithium, sodium and potassium; sulphur, selenium and tellurium, etc. So much interest has been manifested in regard to Prof. Lockyer's announcement, that we have ventured to devote a large space in this department to a brief review of past speculations in this direction by scientists of acknowledged eminence.

It is well known that Faraday, nearly 30 years ago, intimated the probability of such a discovery—even without the hints in that direction lately given out by the spectroscope, an instrument which that noted chemist never lived to see. Possibly that scientist is thought by many to have adopted the theory far more fully than he really did; but fortunately we have quite a full record of what his speculations and investigations in this direction really were, in the *Chemical Record* of July 12th, 1851, in an interesting paper read before the meeting of the British Association of that year by Mr. Dumas. That gentleman was introduced and endorsed by Prof. Faraday, who, in his introduction, in alluding to the reported discovery of a new metal, remarked that he was almost sorry to welcome any more new metals, as his *hopes* were in the direction of proving that bodies called simple were really compound. The remarks which were to follow, by M. Dumas, the Professor said, were on certain curious relations between volume and simple weight, which rendered it probable that certain bodies, called atomic, were really compounds.

M. Dumas commenced by remarking upon the difference in solubility in water of lime, baryta and magnesia. Each was sparingly soluble, but magnesia the least so; while in the form of sulphates, magnesia was the most soluble. Why this difference? The same facts were true in regard to the two chlorides of mercury.

Again, chemical agency is the result of force, which force was at once indicated and measured by combining or atomic numbers; which were in inverse ratio to their power of chemical agency. Thus the atomic or combining numbers of chlorine, bromine and iodine, were respectively 35, 80, 125. Of this triad, chlorine would displace bromine; bromine would displace iodine. The three bodies, too, displayed other symmetrical gradations. Thus chlorine was most volatile, and iodine least; bromine being intermediate; and, as a consequence of the last deduction, chlorine was least dense, iodine most, and bromine intermediate.

Thus we have a triad or series of three bodies, displaying under three several aspects a symmetrical gradation. As chemistry becomes better developed it subjects itself to the scrutiny of mathematical investigation. Can mathematical investigation be applied to the triad of chlorine, bromine and iodine? And, when applied, does it give a result accordant with incipient speculation? The atomic numbers of chlorine, bromine and iodine, evidently supply us with the fairest data on which to exercise our calculations. Now, if there be any truth in these speculations, the atomic or combining numbers of the three bodies in the triad being taken, half the sum of the extremes should be equal to the mean; or half of 35, the atomic number for chlorine, plus half of 125, the atomic number for iodine should equal 80, the atomic number for bromine. And this indeed is the result, as will be evident on reference to the following simple arithmetical sum:

Atomic weight of chlorine	35
Atomic weight of iodine	125
Sum	160

Half of 160=80, the atomic weight of bromine.

"Thus it follows," to use the beautiful expression of M. Dumas, "if we could by any means cause the union of half an atom of chlorine with half an atom of iodine, we might hope to get, to form, to create an atom of bromine!"

Leaving the triad of chlorine, bromine and iodine, M. Dumas next took up a second triad, of sulphur, seleuium and tellurium; bodies which all chemists know to be isomeric—or capable of replacing each other in compounds, and to be endowed with properties mutually analagous. Of the three, sulphur is the most volatile, selenium next, tellurium least of all. As to their decomposing power, sulphur replaces selenium; selenium, tellurium; in short, the remarks already applied to the triad of chlorine, bromine and iodine will apply here.

Do the generalizations of M. Dumas apply? We will see.

The atomic or combining weight of sulphur is 16; of tellurium, 64; the half of the sum of these extremes is the number, 40—and this is the exact atomic weight of the middle term of the triad—the atomic weight of selenium!

Take, again, the triad calcium, strontium and barium. Without stopping to indicate the various analogies of these bodies, it will suffice to point out their general chemical similarity. In this scale of analogous qualities, calcium and barium are the extremes, strontium is the mean. The atomic weights of the three are as follows: Calcium, 20; strontium, 44; barium, 68.

It will be evident at a glance that there is here also a harmony between the chemical qualities and mathematical expouent of their combining proportion as before; for 68 plus 20 divided by 2 is equal to 44, the atomic number of strontium. Thus, to again use the expression of M. Dumas, if by any means we could effect the union of half an atom of barium with half an atom of calcium, we should have as a resultant one atom of strontium!

Let us take another triad: Lithium, 7; Sodium, 23; Potassium, 39. The similarities between the properties of these bodies is too evident to be pointed out; of the three, lithium is the least individualized alkaline metal; potassium the most individualized; sodium, as all know, stands intermediately between the three; and here again, as the most casual examination will demonstrate, the same purity of chemical and mathematical symmetry holds good.

Now, so extraordinary a symmetry of chemical qualities with mathematical exponents can scarcely be assumed to be a matter of chance; still less can it be said that the atomic figures on which these deductions are based have been strained to suit the opinions of M. Dumas.

M. Dumas followed his line of investigation from inorganic triads into those of organic radicals, as follows:

Hitherto we have been confined to inorganic triads. We will now look further still into the recesses of chemical philosophy. It will be familiar to most of our readers that many chemists have regarded certain bodies of compound nature as analogous in many properties to the metals. Of this kind are the three organic radicals: $C_2 H_3 O$; $C_4 H_5 O$; $C_6 H_7 O$; which may be regarded as three several oxides of an isomeric triad, bearing analogy to those already adverted to in the inorganic world. Now, the slightest examination here will prove again that the law hitherto applied holds good in this case. Omitting the oxygen in the three preceding substances, half the sum of the extremes will be equal to the mean.

From the above M. Dumas suggests as a general law: "When three bodies having qualities precisely similar, though not identical, are arranged in succession of their chemical powers, there will be also a successive arrangement of mathematical powers, indicated by the respective atomic numbers of the substances, and amenable to every mathematical law."

In regard to these illustrations and facts, Mr. Dumas further remarked: "That this symmetry of chemical with mathematical function points to the possibility of transmutation is unquestionable—yet not transmutation in the sense of the old alchemical philosophy. Chemists see no manifestations of a tendency of being able to convert lead into silver, or silver into gold. These metals are not chemically conformable. One cannot take place of another by substitution. They do not form an isomeric group. The probability is that our first successful transmutation as regards the metals will effect the change of physical state merely, without touching chemical composition; thus already we have carbon, which, as the diamond and as charcoal, manifests two widely different states. Sulphur also assumes two forms, as also does phosphorus. Then, why not a metal?" This sort of effect Mr. Dumas suggests will be among our first triumphs in the way of dissociation or transmutation.

We may here remark that in a lecture delivered soon after before the Royal Institution, Prof. Faraday, after similarly describing these curious arithmetical relationship, said: "We seem here to have the dawning of a new light, indicative of the mutual convertability of *certain groups* of elements, although under conditions which as yet are hidden from our scrutiny."

DISCOVERY OF A NEW MINERAL.—In examining a specimen of ore from the Silver Islet mine, on the north shore of Lake Superior, recently, Prof. Henry Wurtz discovered that it was a mineral unknown to the scientific world. He analyzed it and found it contained large proportions of silver and arsenic mixed with iron, zinc, cobalt and sulphur. He exhibited specimens of the new mineral, at a recent meeting of the New York Academy of Sciences, and gave to it the name of *Huntilite*, in honor of Dr. T. Sterry Hunt, of Montreal.

THE *Times-Review* describes the late exceedingly rich strike in the 500 level of the Grand Prize.

The Bodie Mine Owners Probably Safe.

Geo. A. Nourso writes to the *Bulletin* on the subject of the Bodie land titles. It has been, he says, many years a question in the land offices and courts whether the United States act granting the 16th and 36th section of each township to the State for school purposes, would hold good when those sections included mineral lands. In Higgins vs. Houghton the Supreme Court of California during the April term of 1864 held emphatically that the 16th and 36th sections went to the State under any circumstances, whatever their character. The case of Sherman vs. Burch has been cited as affirming this decision. That is a mistake, for in this case the land in dispute was agricultural, *not mineral*. Our Legislature has claimed, in accordance with the Higgins and Houghton decision, in the "act regulating the sale of mineral lands belonging to the State," approved March 28th, 1874.

The case most in point is thus stated by Mr. Nourso.

This question came up in the United States Land Office, in the matter of the application of the "Keystone" and other mining corporations for patents from the United States for their mines and mining claims. These were in Amador county, on a section 36.

One Henry Casey had applied to purchase from the State the half of the section 36, which embraced these mines, and the State of California, through him and his counsel, opposed the issue of patents to the mining companies on the ground that the title of the whole section had already vested in the State of California by the school land grant of all sections 16 and 36. No means were left unemployed to impress this view upon the United States land officers.

As attorney for the mining companies, I claimed, among other points, that mineral lands in sections 16 and 36, do not pass by virtue of that grant, but remain the property of the United States. After a contest of great bitterness the decisions of the Land Department of the United States, sustained this view.

The United States Register and Receiver at Sacramento, the Commissioner of the General Land Office of the United States, and finally, the Secretary of the Interior, sustained the claims of the mining corporations, after full and elaborate argument at each stage of the proceedings, adopting this view of the operation of the school land grants.

After the mining companies had obtained their United States patents, the grantee of Cary D. W. Gillett, armed with a State patent for the half section, brought suit against the "Keystone Con. M. Co.," in the Twelfth District Court, for the possession of their mine, which had been in possession of themselves and their grantees for over 20 years.

The action was transferred to the United States Circuit Court (the plaintiff being a citizen of New York), and was tried during the past year before the Hon. Lorenzo Sawyer, Judge of that court, without a jury. It was elaborately argued in printed briefs, and considered by Judge Sawyer with even more than his usual thoroughness—the amount of stake being very large. He rendered an oral opinion thoroughly discussing the matter, and, as one of the grounds of his decision in favor of the Keystone Co., he held that the school land grant of March 3d, 1853, was not intended to embrace, and does not embrace any sections 16 or 36 which are mineral lands.

As yet there has been no writ of error sued out in this case. If it shall go to the Supreme Court of the United States, we shall probably have a final decision of this mineral land question. I cannot doubt for a moment that Judge Sawyer's decision will be sustained.

Mining Share Market.

The stock market continues dull and heavy, not the slighest animation being apparent. This state of affairs is in strange contrast with the excitement existing a few months ago, when everybody was going to make a fortune in shares. How the brokers make both ends meet, it is difficult to say, but it is not probable that we shall have any very sharp rises or falls for a while yet.

As far as the Comstock is concerned the work of development continues, more particularly in the direction of pumping, however, and draining mines, with no present startling results in the way of dividends. The flow of water is very strong in most of the principal mines. The lightning drift of the Hale & Norcross will connect with the Combination drift in a couple of days more. After that it will probably take some time to get everything in readiness, when it will take but a very short time to rid the flooded mines of water and give a chance to get at and develop the ore prospects known to exist on the lower levels of both the Savage and Hale & Norcross mines.

Spanish brigands have been troubling France.

Ex-Governor Bravo, Mexican revolutionary leader, has been killed.

It is semi-officially reported in Vienna that Russia has promised to evacuate Bulgaria and Roumelia the first of April.

The plague in Astrakhan has lately increased in virulence.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

Plymouth.—The Jackson *Dispatch* of Jan. 4th reports that the Empire mine is still pauning out her regular returns of $20,000 to $30,000 each run.

Marble Quarry.—*Ledger:* The machinery has been thoroughly overhauled, new saws put in, T railroad iron laid for the cars to run on (which is a great improvement upon the old style of sheet-iron track), also new blocks and tackle rigged for the hoisting apparatus. On account of the lack of water, the saws are at present run by steam. The quarry, under the supervision of W. H. Coleman, is steadily improving, the marble being softer and whiter, according as the quarry is developed. There are now hundreds of tons of excellent marble in sight.

Coney Mine.—Jackson *Dispatch*, Jan. 4: This mine, which has been lying apparently dead for about nine years, we understand will certainly be started up in a very short time. It is said that excellent new machinery has already been engaged and will likely be here in a few days. A mill site has also been located just below the mine, where an excellent water power can be obtained from the Moore mine ditch. The working of this mine, which our people have so long expected and desired, will prove of much importance to Jackson, as it will doubtless give employment to quite a number of miners and workmen. The mine is principally owned by Dr. Zeile, of San Francisco, a man of immense wealth, and one of great mining experience. The mine, we believe, is hereafter to be known as the Zeile mine.

Other Mines.—The shaft of the Good Hope is to be enlarged and retimbered. The Moore mine ditch is now nearly ready for the laying of the pipe, most of which is now on the ground. It is reported that the Seaton mine, near Drytown, has been bonded for five years, by the English company that own the Original Amador. Parties have been negotiating for some time with a view to purchase the Crown Point and Bonanza mines, at Drytown. Good rock is being taken from the 1100 foot level of the Oneida. Sulphurets from this work are being hauled from this mine to Garland's works, at Sutter Creek.

CALAVERAS.

The Upper Country.—*Chronicle*, Jan. 4: Six tons and a half of ore from the Buffalo mine near West Point, owned by Reed & Robinson, crushed in Harris' mill at Sandy Gulch, yielded 35 ounces of gold. That is an average of about $100 per ton; 13 tons were taken out altogether and the rock divided between the two partners. We did not learn how much the other portion of the ore paid. Nine tons of rock from F. Costa's mine, located near the North Fork of the Mokelumne, near West Point, yielded 61 ounces—an average of about $121 per ton. Seven tons of ore taken from Bill Deryer's mine, in the same district, paid 42 ounces.

EL DORADO.

Kelsey.—Placerville *Democrat*, Jan. 4: An expert has lately examined the Gold Deposit mine. The tailings from the mill assayed $44 per ton, and the sulphurets "went way up," some samples reaching the enormous sum of $24,000 per ton. It has been decided by the company to let the mill stand inactive until the concentrating works are up, as it is evident that all the sulphurets are very rich, and so long as there is any loss of them there will be a corresponding loss of gold. In the meantime the sinking of the shaft will be prosecuted as fast as heretofore, so as to bring as large a body of ore in sight as possible. The Estrella mine will probably be placed on a working basis in a short time. From the well-known richness of this mine it is quite strange that it should have lain idle so long. The lode is one of the largest in this section. It has been prospected to a depth of 50 feet, with good prospects.

LOS ANGELES.

Gold in our Streets.—*Herald*, Jan. 4: Some excitement was created in Los Angeles New Year's day by the discovery, on Olvera street, near the Hotel di Roma, in the public roadway, of placer gold, of a very promising appearance, by Councilman John Shaffer. That gentleman's attention was attracted to some specks of free gold which was made apparent by the wash of the late rains. He procured a shovel and pan and went to work. From a single shovelful he washed out wire gold to the value of 25 cents. Later in the day other prospectors started in, and one amongst them washed out a nugget of virgin gold which weighed $1.25. Claims have been staked out in the neighborhood of the discovery, and our very streets are liable to be uprooted in the eager quest for gold. Mr. Pelanconi says that when he was making the excavation for his cellar, free gold was frequently seen by the workmen. In every case actual washing out resulted in a yield of from three to ten cents a pan. It is just possible that the rocker and pan of the old mining days may soon become a familiar spectacle in our streets. We shall await future developments with an absorbing but kindly curiosity.

MONTEREY.

Mount Carmel Coal.—Salinas Valley *Index:* The latest developments and a thorough examination and survey of all outcroppings show a most favorable result. There are three distinct veins—the east, center and west vein—averaging from four to nine feet in thickness. The quality of the coal is equal, if not superior, to any in the California market. It sells for $10 per ton in San Francisco, and the screenings bring $6, which is better than Australian coal. It burns with a strong, steady flame and is an excellent steam generator. At present the facilities for getting the coal to market are very primitive; but a railroad has been decided upon, which will better matters greatly.

MONO.

The Bodie *Chronicle* of Dec. 28th reports as follows on the mines:

Standard.—Latest official report is that the crosscut east from the main shaft is in 85 feet; progress for the week 22 feet. At a point 70 feet from shaft a ledge was cut which is three feet wide. The south drift from this crosscut has been advanced during the week 13 feet, total length, 63 feet; ledge four feet wide. The east crosscut being run on the 300 level south of incline is in 112 feet. Raise north of incline on same level is up 95 feet. The ledge is three feet wide and looks well. The stopes continue to look well, and yield the usual quantity of ors. Mill is running steadily.

Con. Pacific.—The south drift in No. 1 is in 30 feet and ore improving. Drifting for stations to take out ore. Commenced sinking this week in No. 2; down five feet. Main shaft down 159 feet; progress this week, 12 feet. Work progressing satisfactorily.

Mono.—Shaft down 370 feet; bottom shows seams of quartz and much clay, and works well. The crosscut is in 130 feet; the face shows some small streaks of low grade ore, lying very regular, and dipping to the east. Indications are favorable for nearing the vein. Everything is working in excellent order, and a six months' supply of timbers, lumber and fuel is on hand.

University.—Shaft down about 143 feet; drift in 145 feet. Good ledge which assays well, and the prospects are good. A whim will soon be erected. H. E. Ashley has been appointed Superintendent.

Booker.—Shaft down 335 feet; rock hard and little water.

Jupiter.—This mine is east of, and joining the Bodie. The shaft is down 136 feet, and is two compartment, 4x4½. At 126 feet a fine looking vein of three feet, with promising assays indicating a valuable mine, was struck.

Tioga.—Shaft down 360 feet in favorable formation; vein nice-looking, 13 inches wide in bottom, with fair prospects. West crosscut in 38 feet; cut a six-inch seam of quartz, low assay. East crosscut in 45 feet; also have a seam in this cut, with low assays. The hoisting works are in good condition, and everything goes well.

South Bodie.—Shaft, double, down 381 feet. At 351 feet past ledge; drifted 10 feet, then resumed sinking to crosscut at 500 feet. Progress this week 15 feet, the rock being hard.

California.—Sbaft down 140 feet; east drift in 36 feet; west, 24 feet.

Bulwer.—Ledge in south drift is two and a half feet wide and continues to look well. The Stonewall stopes also present their usual good appearance. Have shipped to date 405 tons of ore of good quality to the Bodie mill.

NEVADA.

Jacobs and Sargent.—Nevada *Transcript*, Jan. 3: The shaft of the Quaker hill claim is down 200 feet, and a drift has been run along the bedrock in a westerly direction for 250 feet. From the end of this an upraise is to reach the gravel. A few hundred feet from the present shaft, large quantities of gravel, paying as high as $5 per ton, have been taken out.

Plum Valley.—A tunnel has been run 100 feet; a shaft sunk 80 feet. The ledge in the tunnel is two feet wide; 100 tons of very good rock has already been taken out. All this has been done since June last.

Items.—The *Herald* says, that it is not unlikely that the whole property of the Empire M. Co. will go to the hammer on the 18th inst. The Nevada County Mining Association have leased the North Star mine, and will promptly resume work in spring. In 1871 this mine divided $76,500 among its shareholders. The Swiss American company will soon start up work again on the Victor, Massachusetts hill. The Pacific mine is being worked on tribute, the lessees paying 55% of the mill proceeds. There is no new development from the New York hill mine. The Rocky Bar is still taking out rich rock. The Scadden Flat M. Co. has completed the erection of its extensive machinery, and will push ahead vigorously. Mr. John Pattison has gone up near Omega to select a suitable place for starting a tunnel, on the ground of the Nevada B. G. Con. M. Co. The new mine on Little Deer creek, the Lincoln, has a ledge from 10 to 12 inches thick; and will in a short time have ample water power. Four pans from Shearer & Co.'s claim in the Round Mountain mining district, lately yielded $1.50. It is said that signs of richness and permanency in this district increase daily. The Yuba River M. Co. have run a tunnel 300 feet under the river, at Long's Bar, and struck gravel that pays $3 to the pan.

Mining Under Yuba River.—*Herald*, Jan. 4: The following claims are located along the river, the object of whose owners is to reach the beds of the present river channels: Yuba, Long Bar, West Point, Nichols' claim, Olmsted, North Star, Sand, Flat, Ohio and Tennessee. These companies are all corporations, and the larger part of the stock is held in Grass Valley. There are many places under the late river channels which have never been worked, the tailings from the larger mining operations above coming down and covering them up. Formerly miners tried working these places by wingdams and other contrivances to turn the water when it was low, but the debris has become so deep that it took nearly all summer to get down where the good pay was, and then the high water would come and wash away the dams and fill up the holes so that the same work would need to be repeated each summer, and the gravel has become so deep in the modern river beds that it made the season too short to enable advantageous work. Now a shaft is sunk on the bank and tunnels are run under the river bed, in search of pay gravel.

SAN LUIS OBISPO.

Placer Mines.—San Luis Obispe *Tribune:* In the eastern portion of township No. 30 south, range No. 16 east, Mount Diablo meridian, about five miles S. W. of the La Pansa ranch house, well up, and contiguous to the highest peaks of the Pansa mountains, on the headwaters of a creek emptying into the Estrella creek a couple of miles to the south of Pausa, the San Luis Obispo placers are located. They were discovered in last September by a man named Trujillo. As yet gold in paying quantities has been found only in Trujillo gulch and one tributary. From the forks of the creek where the discovery was made, gold has been found and claims staked off extending down the ravine a distance of three quarters of a mile, and up the north and south forks each, for perhaps half a mile near their sources where they debeuch from the main sierra. The character of the gold is what is generally termed coarse, ranging from a color up to chunks of $20 and $25. A nugget weighing $25, with some particles of quartz attached, and containing perhaps $20 of pure gold was found. There is, however, some mystery clinging to this nugget. The quartz ledges from which this placer gold has been washed have probably not yet been discovered, though some good looking rock has been located. On Dec. 16th a district was organized, to be known as the San Jose and La Pausa; headquarters at La Pansa. Messrs. Carroll, Garcia and Lopes were appointed to draft rules and regulations. Says the Salinas City *Index:* The San Jose valley above referred to is situated on the headwaters of the Salinas river, 20 miles in a southeasterly direction, from Santa Margarita, ensconced between the La Pansa mountains on the north and east, and the Santa Lucia or Coast Range on the south, with the main branch of the Salinas river running through the southerly and westerly portion. Surveyor E. K. Harris, of San Luis Obispo, says: "There are two routes leading to the new placers, either by the way of San Jose valley, where wagons will have to be abandoned, and horse or foot resorted to over the rough mountain trail already described; or the more roundabout way, by the Rocky canyon, Mitchell's and La Pansa. Those traveling in wagons I would advise to take the latter route, as a pretty fair wagon road leads to within one mile of the mines."

SHASTA.

Furnaceville.—Reading *Independent*, Jan. 2: Clark & Co. have commenced work on the "Homestake" claim. This claim was the first location made in this district, several years ago—then known as the "Silver Creek Ledge"—and, of course, as the district went down, the claim was abandoned. The mill or furnace then constructed (burned down in 1871 by mountain fires) was supplied with ore from this mine, the assays being favorable. The ore obtained is richly argentiferous galena; but the company used what they called a "water blast," and produced a heat so intense that the valuables escaped in the form of vapor.

NEVADA.

WASHOE DISTRICT.

Con. Virginia.—Gold Hill *News*, Jan. 8: The southwest drift at the 2150 station of the C. & C. shaft is now in 118 ft., and is advancing 4 ft. per day, the face still in blasting porphyry. On the 1900 level the station in the joint east crosscut on the Best & Belcher line is completed, and sinking the winze to connect with the level below has been commenced. This crosscut will now be continued to the eastward to better define the eastern limits of the ore vein in that direction.

Ophir.—Daily yield, 70 tons of ore. The ore stopes on both the 1900 and 2000 levels continue to show well and yield rich ore. The severe freezing weather still continues to interfere very materially with the operations of the Carson river mills.

California.—Daily yield, 340 tons of ore. This ore is being reduced at the California mill as fast as it is extracted, and gives good returns. The usual monthly dividend of $1 per share, aggregating $540,000, was declared yesterday. The ore stopes still continue to look well.

Julia Con.—But little progress has been made during the week in the main southwest drift on the 2000 level. The flow of water from the face is yet both strong and hot. The water as it flows from the drill holes shows a temperature of 75° to 80°. The last set of holes fired in the face of the drift threw out quartz showing fine veins of ore which give excellent assays in both gold and silver. The flow of water is so strong and hot that the pumps are kept busy to prevent flooding.

Sierra Nevada.—The stone foundations for the new air compressor are rapidly nearing com-

Continued on page 28.

Mines and Works of Almaden.—No. 17.

Translated for the PRESS from "ANNALES DES MINES."

The results obtained from the Idria furnace have been already given. We will only recall that the loss of mercury was definitely proved not to go beyond 5.59% of the mercury contained.

The Pellet furnace gave for 114 tons of ore, of a contents of 8.30%, containing 9,466.134 kilograms of mercury:

	Kilograms.
Mercury coming directly to the store house	7,660.55
80% of mercury from residues	470.714
Total	8,135.264

Loss, 1,330.872 kilograms, which is 1.16% of the ore, and 14.05% of the mercury contained.

The expense of treating 114 tons of ore were:

In the Idria furnace	371.80 frs.
In the Pellet furnace	1,518.00 "

The Pellet furnace was much inferior also to the Idria furnacs from the point of view of hygiene; 35 workmen fell ill, attacked by ulcerations of the throat, the first results of mercurial vapors during the running of the new furnace in May and June.

Condemned a first time, M. Pellet did not acknowledge himself beaten; in spite of the considerable expense of the first trial, in spite of the inutility of attempts to prevent a loss which did not exist, he obtained in 1872 a new seeries of comparative tests under the direction of MM. Luis de la Escosura, Inspector-General of Mines, and Federico de Botella, Engineer in Chief. The tests had two objects: First, to judge of the value of the Pellet system, which was once more, and this time irrevocably condemned, and then to study for themselves the methods of treatment with the Idria and Bustamente furnaces.

The details of these tests have not been communicated to me, they will make the object of an approaching publication of M. Luis de la Escosura: I know only that they have been made with a most minute attention, in order to determine with the utmost exactness the contents of the charges, their weight, the weight of the products of all kinds, that they have determined with precision the temperature of the gases and the rapidity of the current at different points of the entire apparatus; finally that the losses of treatment have been found as 5½% for the Idria furnace, and 4.95% for the Bustamente furnace.

This last figure does not, it is true, represent the exact loss in the current operations, it was obtained in the experiments under conditions therefore of particular exactness; but it indicates that which may be, that which should be demanded of the Bustamente furnace, without modifying either the treatment or the furnace.

Not being able to reason upon the figures of the tests of 1872, we return again to those obtained in 1869 by M. Monasterio. We can arrive with him at a deduction not only of the loss from the metallurgical treatments, as compared with assay values, but also by a sort of synthesis, the loss as compared with all the mercury really contained in the ore.

Let us see in what manner:

The ore is a quartzite more or less impregnated, or a schist more or less spotted with cinnabar. It contains carbonaceous matter (in the schist and in the black quartzite), a little iron pyrites, of native mercury, and of horn quicksilver. According to the manner in which these substances behave in the roasting, we may divide them into fixed and volatile substances, (mercury, sulphur, water, etc).

The residue of the roasting at the Idria furnace has given for 114.000 kilograms of ore, 102,336 kilograms of slag, or 89.768% of fixed matter and 10.232% of volatile matter.

Or, if in the assays of the laboratory, the determination of the richness in mercury is difficult to obtain with a very great precision, it is not so with regard to the fixed matters, and we can from this last weight deduce that of the volatile matter.

We will neglect in this calculation the possible presence of a small quantity of native mercury and of chloride of mercury; we admit that all the sulphur disengages itself in the state of sulphurous acid; we do not take account either of the sulphur of the iron pyrites, partially replaced by oxygen during the roasting, or the carbon of the ore; these two last simplifications will have for a single effect the augmentation to a small amount, the figure which calculation will give us for the mercury.

We suppose then, in short, an ore reduced to these essential elements:

Fixed matter, cinnabar, water. We can not take the water which is contained in the ore as it comes from the mine, and which exposure to the air in winter and in the times of rain can not but augment. The memoir of M. M. Bernaldez and Figueroa gives upon this subject the following figures:

	Contents in Water.
Metal and China of 1st class	0.08%
China of 2d class	0.08%
" " 3d "	0.15%
" " 4th "	0.20%
" " 5th "	0.25%
" " 6th "	0.50%
" " 7th " and solera	0.70%

The proportion of water is the greater, the smaller the amount of mercury there is present, because the poor ores are argillaceous, and therefore retain better the moisture than the rich and quartzose ore. Now the roasting of the ore in the muffle at a temperature gradually increasing, with a strong fire at the end of the operation, in such a manner as to expel all the volatile matter, has given for the different assays taken:

Classes.	Fixed Matters.	Volatile Matters.
Metal and China, 1st Class	70.00	29.10
China, 2nd Class	80.09	19.01
" 3d "	82.75	17.25
" 4th "	89.29	10.71
" 5th "	93.40	6.60
" 6th "	96.00	4.00
" 7th "	97.00	2.40

If now we subtract from the figures giving the total volatile matters the ones just given for the water, there remains for contents in sulphide of mercury:

	Sulphide of Mercury.
Metal and China, 1st Class	29.02
China, 2d Class	10.83
" 3d "	17.10
" 4th "	10.51
" 5th "	0.35
" 6th "	3.50
" 7th "	1.95
Solera	1.70

And as the sulphide of mercury contains 86.29% of mercury and 13.61% of sulphur, the different classes of ore contain:

Metal and China, 1st Class	25.04	While the assays at the laboratory have given:	25.00
China, 2d Class	17.11		17.06
" 3d "	14.75		14.66
" 4th "	9.07		8.88
" 5th "	5.48		4.99
" 6th "	3.02		2.46
" 7th "	1.68		1.03
Solera	1.40		0.80

We shall return to these last figures in an instant, in order to draw from them some consequences from this point of view with regard to the essaye of cinnabar in the laboratory.

Let us calculate now from the preceding figures the complete composition of the 114,000 kilograms employed in the experiments in question. We find then:

Quantities Treated.		Weight of Matters Contained			
		fixed mat'rs	Water.	Sulphur.	Mercury.
		Kilog.	Kilog.	Kilog.	Kilog.
1st Class	21,050	14,945.72	10.864	383.084	5,728.432
2nd "	9,840	7,830.856	7.872	207.643	1,083.624
3rd "	8,920	7,381.300	13.380	209.630	1,315.700
4th "	3,100	2,821.564	6.820	45.504	286.012
5th "	4,480	4,184.320	11.200	38.976	245.504
6th "	5,400	5,184.000	27.000	25.920	163.080
7th "	32,500	32,031.72	234.040	90.594	583.136
Solera	27,000	26,907.60	139.200	66.240	402.960
Total	114,000	101,967.08	510.476	1,583.398	9,939.048

The practical operation gave a residue of 102,336 kilograms of slag, 368.92 kilograms more, consequently than calculation would indicate.

Proportion of slag produced	89.768%
" calculated	80.444%

Admitting even the most exact weighing of the slag, we might explain this very small difference, by the small amount of mercury retained in the slag. We can then with fear of being deceived in the least, take the figure of 9,939.048 kilograms as representing the maximum of mercury, contained in the 114 tons of ore. The loss from the assays would then be at most, 0.41% of the ore, or 4.75% of the mercury contained. Finally, the loss of the metallurgical treatment would be 1,002.264 kilograms, out of the 9,939.048 contained, or 10.08%, at a maximum. There is besides the amount of the loss determined by the contents as given by the assays, here 5.59%, which is truly entitled to be taken into consideration in an industrial operation.

Let us return for a moment to the contents given by the assays, at the laboratory, in order to compare them with the results of the preceding calculation. The following table gives the absolute, *A* the relative loss from the assays; we should not forget also, that these figures are the maxima.

CONTENTS OF ORE IN 100 PARTS.				DIFFERENCE, Or Loss from Assay.		
	Calculated.	Assay A.	Assay B.	Value taken as most exact	Absolute.	Per Cent of Mercury Contained.
1st Class	25.04	25.00	24.95	25.00	0.04	0.160
2nd "	17.11	16.90	17.06	17.06	0.05	0.290
3rd "	14.75	14.60	14.66	14.66	0.09	0.610
4th "	9.07	8.84	8.88	8.88	0.19	2.050
5th "	5.48	5.39	4.99	4.99	0.49	8.941
6th "	3.02	2.39	2.46	2.46	0.56	18.543
7th "	1.68	1.04	1.05	1.05	0.63	37.500
Solera	1.46	0.51	0.80	0.80	0.66	45.205

The assay marked *A*, was made at the assay laboratory, of the school of mines, at Madrid; the method employed, was the distillation of ore mixed with iron filings. The assay marked *B*, was made at the laboratory, at Almaden, by mixing the ore with its volums of quicklime, and one-tenth of its volume of carbonate of soda. The figures of the fourth column, are the result of the two preceding ores. We have always taken the higher figure, as the one approaching more nearly to the truth. The fifth and the sixth columns, show the losses absolute, as well as relative, they increase as the richness of the ore assayed diminishes. This result is in accordance with that of the experiments of M. Glowaky, at Idria, cited by M. Huyot, in a memoire in the *Annales des Mines* in 1854, (Fifth serie, stome V.) and in general with the results of all assays, which give contents more and more inexact in the same ratio, as the ors becomes poorer.

The reasoning which leads to this conclusion is, it is true, not very convincing for the poorer ore, which may contain other volatile matters, as well as sulphur, mercury and water, in quantities hardly to be neglected in comparison with the small quantity of mercury which the ore contains.

Without then wishing to give to this discussion a weight which it in reality does not possess, we limit ourselves by repeating in resume:

1st. That the averags contents of the ore at Almaden does not go beyond 8% to 9%.

2nd. That the loss of mercury indicated by the assays does not go beyond 6% in the Idria furnace, and 5% in the Bustamente.

3d. That the loss of mercury contained, in calculating this from the most elevated figure, does not go beyond 10%; and in conclusion,

4th. That with regard to the apparatus in use at Almaden, while we cannot assuredly wish to call them less irrational, at the same time they do not present to such a high degree the defects with which they have been credited, or at least they have been much exaggerated, and that conducted with care, they give with a rich ore excellent results.

Is this saying, for that matter, that they should give up attempts at improvement, or that other works as those of Idria should obey a prejudice in abandoning them for a long time back? We do not think so. The difference in the nature of the ores treated at Idria or in California, can suffice to explain the difference of the results obtained and the abandonment of the apparatus of Almaden at Idria and elsewhere.

In the presence of the actual change of opinions of the Spanish engineers, upon the processes at Almaden, it is certain that a long time will pass before they dream of introducing any innovation of considerable importance; the great expense caused by the relative experiments of the Pellet system has put off for a long time all desire to make new trials. They do not give up, however, the idea of improvements which may be some time introduced into the treatment.

The following are some of the principles which M. Monasterio would have been in favor of applying when the opportunity offered to the solution of the problem:

1st. Continuous roasting. 2d. Absolute separation of the gases of the fire from those coming from the ore. 3d. Condensation with the aid of water in tubes of iron lined on the inside in such a manner as to protect them against the action of sulphuric acid, and bathed on the outside with water. 4th. Artificial draft. 5th. Separate treatment of the residues in retorts of iron or clay.

It is possible that some of the ideas of M. Monasterio may be applied when the results of the processes in use in America, on which they are actively engaged, are sufficiently known at Almaden.

But it is not my intention to extend myself at length upon the reforms which exist only as projects, and whose trial consequently will not be made for a long time.

[To be Continued.]

THE CLIFTON COPPER MINES.—On the eastern frontier of Arizona, at the town of Clifton, Yavapai county, near the New Mexican line, 500 miles east of Yuma, is one of the richest copper mines on this coast. So easily worked and so rich are the ores that it pays to transport them by team several hundred miles across New Mexico to Trinidad, Colorado, whence they are shipped by rail to Baltimore. The mine is in the hills some distance from the town, and the ore is carried in sacks on mule-back to the reduction works, some nine miles by the circuitous trail. The proprietors of the mine are about to build a railroad of 20-inch gauge for the purpose of saving this expense. The road will be five miles in length and will be the first narrow-gauge railroad in the Territory. Capt. N. S. Davis, a pioneer Californian and a well-known civil engineer, started shortly before the holidays to make the surveys and begin the construction of this road. He is under engagement for one year.

POSTMASTERS of the fourth class have been allowed commission on stamps sold. They will now be allowed commission on stamps cancelled on letters instead. It is believed that this change will increase the postal revenue about $900,000 per annum.

THE Mexican government has made arrangements for the payment of the third instalment of $300,000 indemnity to American citizens, due this month.

THE ENGINEER.

The Strength of Locomotive Boilers.

In view of the recent explosion of a locomotive boiler on the Central Pacific railroad, near the Summit, the following extract in regard to the sources of weakness in locomotive boilers, will be read with much interest by mechanics and engineers. The extracts are from a very suggestive article in the *Railroad Gazette* of Dec. 20th: Of late years, owing partly to the increase in the size of locomotive boilers, and partly to the numerous explosions that have occured, the thickness of boiler plates has been materially increased. Twenty-five years ago there were few, if any, used thicker than 5-16 in. Now, for the larger sizes of locomotives, plates are always ⅜ and in some cases 7-16 in. thick. Double-riveted seams were seldom found in the older boilers, whereas, now, it is the rule for horizontal seams, and in some cases for all others; and in the larger engines now in process of construction on the Louisville & Nashville railroad the former are treble-riveted. The object of this increase in the thickness of the material and in the method of fastening it together is to increase the strength of the structures; but a boiler is like a chain, the strength of which is only equal to that of the weakest link, and the misfortune has been that in attempting to increase in resisting capacity of boilers, some of the links have been very much neglected. A house painter who should fall from a scaffolding by the breaking of a rope would quite naturally get a stronger one if he survived the fall; but the strong rope would be of little service unless it were securely fastened. Without knowing any confirmatory facts it is safe to venture the opinion that many more accidents of persons falling from scaffolds are caused by insecure *fastenings* than by insufficient strength in the members of the structure. The unfortunate man who undertook to lower his wife from the window of an upper story of the Southern hotel at the time it was burned was not mistaken about the strength of the pieces of bedding which he tied together, but he had not the knowledge nor the skill to fasten them, and his knots slipped and his wife was killed.

The weakness of boilers arises generally not from insufficient material, and perhaps not as often from inferior quality, as it does from the weakness of the attachments of the various parts. Unless there is some reason for a contrary opinion, it may be assumed that riveted work will always be done badly. The chief defects of such work are out of sight, and to a great extent undiscoverable after it is finished. Mismatched and unfilled holes cannot be seen after the heads of the rivets are formed, and therefore such work is less subject to criticism and inspection, and consequently there is little rivalry or pride of excellence in doing it among mechanics. Without the very closest inspection it is always possible for a workman to hide his blunders and his carelessness. Then, too, there is no strong sense of the necessity of good work of this kind. There is generally a lack of what might be called mechanical moral sense in this respect, and an engineer who should insist upon having first-rate work would find it no easy task to have his orders executed.

In the construction and attachment of the braces, there is more carelessness and ignorance displayed than in any other part of boiler construction. These are seldom carefully designed, and are nearly always left to workmen to arrange. They are seldom deficient in the amount of material of which they are made, but very often in the methods of attachment to the shell of the boiler.

In the attachment of steam domes there is more disregard of the laws which govern the strength of locomotive boilers than anywhere else. In order to give access to the inside of the boiler a hole from 24 to 30 in. in diameter must be cut into the shell. To make up for this there is the flange which is formed on the base of the dome, and, in some cases, another flange which is turned up on the plate which forms the shell of the boiler. Both of these are cut away by the rivets so that their sectional area is diminished thereby. What is needed here, and what is used in Europe, is a heavy wrought-iron ring around the hole at the base of the dome. This can be riveted either to the boiler shell or to the dome, and in this way it will reinforce the strength of the boiler which has been diminished at this point.

Broken stay-bolts we have always with us. Our present knowledge of the subject has not been far supplied a remedy for the evil. All we can do is to supply such means as will enable us to discover the breakage as soon as it occurs. Hollow stay-bolts plugged on one side are the surest safeguard.

It is a little singular that more effort has not been made to overcome the effects of unequal expansion in locomotive boilers. If we reflect for a moment on what occurs when a fire is built in a locomotive boiler filled with cold water, it will be seen that there must be enormous strain exerted on it before the whole of it becomes heated. The first effect of the fire is to heat the fire-box plates and tubes. These must expand before the outside shell is even warmed. The expansion due to a rise of temperature from say 70° to 400° is about 0.002 of the length of the tube, which if 10 feet long would therefore be increased in length nearly a quarter of an inch. This pressure must be

exerted against the front and back tube-sheets and transferred to the shell of the boiler. The front tube-sheet cannot yield excepting to an almost inappreciable amount. The outside shell will be stretched and the tubes compressed somewhat under the strain, but after making allowance for these effects it will be seen that the greater part of the strain, due to the elongation of the tubes, must be exerted on the back tube-sheet, and this in turn is transmitted to the side-sheets and stay-bolt of the fire-box. It is no wonder they are broken.

It is remarkable that no one has devised any method of compensating or permitting this expansion of the tubes without subjecting the other parts of the boiler to excessive strains.

It seems as if there were some grave defects in the principles of constructing locomotive boilers. Whether they can be remedied it is too early to answer, but it is certain that much of the workmanship and the design of the details could be immensely improved without any increase of knowledge on the part of those who have charge of their construction, excepting that which every good mechanic should have, and which can be found in elementary books.

Boulder County Ore Product for 1878.

The *News and Courier* of December 27th, is authority for the following: On account of the many channels for the disposal of ore, especially the smaller lots of the higher grades—which in the aggregate amount to no mean sum—it is somewhat difficult to arrive at the ore product of a given section. Below, we give an approximation of the larger amounts which have been purchased, or treated within the county and handled as bullion, for the year just closing:

Bullion shipped by express up to the 20th inst.	$314,519.00
Same (estimated to end of year)	10,000.00
Purchased by Boston & Colorado Reduction Company's works at Black Hawk, for 10 months ending with October: Gold, $178,-000; silver, $73,000	250,000.00
Same, at Argo works for months of November and December (estimated)	50,000.00
Paid by Golden Smelting Company up to 23d inst., net	40,123.50
Add deductions for loss and treatment (estimated)	8,000 00
Small lots of rich ores shipped to Omaha and Newark, say	10,000.00
Ores shipped to other points, say	10,000.00
Bullion sent out of the county other than by express, say	20,000.00
Total	$713,642.50

This will probably be rather under than over the actual yield. The Trenton works at Golden are supposed to have purchased some ores in the early part of the season, and probably some of the Denver works bought small lots. The shipments to Omaha and Newark have fallen off largely of late years, but we are assured that they still receive occasional lots. Boyd's product all goes into the express company's shipments. But private individuals are often intrusted with small lots of bullion which are not thus accounted for. We are indebted to Prof. Gregory Board, of the Golden works, and to Mr. H. R. Wolcott, of the Black Hawk works, for some of the figures herein given.

SILVER CLIFF.—Carl Wulsten, in a letter to the Denver *Tribune*, dated, Rosita, Custer county, Dec. 8th, says: Silver Cliff to-day is as good a mining camp as Colorado can show, and its horn silver deposits will yield millions before they play out, if they ever will. I declare that they will turn into good silver bearing veins when properly developed. I have found horn silver with the same rock as at the Cliff eight miles from the Cliff and have traced the belt for 14 miles now. I have sauntered along the obsidian belt and made several valuable discoveries since I was last in the Cliff four weeks ago, and I am more than ever satisfied that the Silver Cliff mines will hold out, and that their belt extends southeast 14 miles. How does it happen that this same obsidian formation shows such regular extent and upon a straight southeast course? Is that evidence of a mere deposit or of a stratified volcanic dike in regular extension?

SINGULAR OCCURRENCE.—The fishing smacks along the coast of Florida, report a stream of fresh or poisonous water along the coast, that kills all the fish in its range. They report sailing for 200 miles through dead fish, covering the sea as far as the eye could reach with all the varieties. Immediately on the shore the water is salt and natural, while less than a mile off it appears of a red brick color.

PROFIT ON COINAGE.—After buying the silver for coinage, paying for the transportation, and allowing for wastage in the process of coinage, since the commencement of coinage of the standard dollar the Government has profited, between the legal tender value and the real value of bullion which it contains, to the amount of about $1,600,000.

COST OF THE ELECTRIC LIGHT.—The cost of the 16,000-candle power electric light at the Palace hotel, San Francisco, has been estimated as follows: Interest on the investment, wear and tear of the machinery, etc., is estimated at 1½ cents; cost of coal, 40 cents; carbon, 28 cents engineer, 10 cents; oil, etc., 3 cents; total, $1.25 an hour.

A NUMBER of horse cars were lately shipped to Calais, France, to be used in running from that place to the suburb of St. Pierre, over a road constructed with English capital. Orders are expected soon from other European cities.

Useful Information.

GLASS MILLSTONES.—The *Manufacturer and Builder* calls the attention of manufacturers who cast heavy pieces of glass, and also of millers, to a recent German discovery, that the finest flour is produced by those millstones which have the most glassy texture and composition, and the consequent discovery that pieces of glass combined in the same way as the French burr, and similarly grooved on their surfaces, will grind better than the burr millstones. The consequence of this discovery has been the invention of the glass millstones now made by Messrs. Thom, and used in Germany and Borkendorf with great satisfaction, as it is found that they grind more easily and do not heat the flour as much as is the case with the French burr stone. In grinding grist they run perfectly cold. In order to make such stones, blocks of glass of from six to twelve inches wide are cast in a shape similar to the French burrs, but more regular and uniform. They are connected with cement in the same way, and dressed and furrow cut with picks and pointed hammers; but it is believed that diamond-dressing machines might be profitably applied. It is said that these millstones, made of lumps of hard glass, do not wear away faster than the burr stones. Stones of four and a half feet in diameter, driven by six-horse power, ground 220 pounds of flour an hour, and did it remaining cold. The grist is drier, looser, and the hull more thoroughly separated from the kernel than is the case with other stones.

TO PREVENT RUST.—Prof. Olmstead, author of "Olmstead's Natural Philosophy," gives the following as a preventive of rust: For farm implements of all kinds, having metal surfaces exposed, for knives and forks, and other household apparatus, indeed for all metals likely to be injured by oxidation or "rusting:" Take any quantity of good lard, and to every half pound or so, add of common resin ("rosin") an amount about equal to the size of an egg or less—a little more or less is of no consequence. Melt them slowly together, stirring as they cool. Apply this with a cloth or otherwise, just enough to give a thin coating to the metal surface to be protected. It can be wiped off nearly clean from surfaces where it will be undesirable, as in the case of knives and forks, etc. The resin prevents rancidity, and the mixture precludes the ready access of air and moisture. A fresh application may be needed when the coating is washed off by friction of beating storms or otherwise.

DEPTH OF ROOTS.—Mr. Foote, in Massachusetts, has traced out the tap root of a common red clover plant downward to the perpendicular depth of nearly five feet. Hon. J. Stanton Gould followed out the roots of Indian corn to the depth of seven feet, and states that onions sometimes extend their roots downward to the depth of three feet; lucerne, 15 feet. Hon. George Geddes sent to the museum of the New York State Society a clover plant that had a root four feet two inches in length. Louis Walkoff traced the roots of a beet plant downward four feet where they entered a drainpipe. Prof. Schuhart found the roots of rye, beans and garden peas to extend about four feet downward; of winter wheat, seven feet in light subsoil, 47 days after planting. The roots of clover one year old were three and a half feet long; those of two year old plants four inches long.—*Factory and Farm.*

CEMENT FOR LEATHER.—Of many substances lately brought very conspicuously to notice for fastening pieces of leather together, and in mending harness, joining machinery belting, and making shoes, one of the best is made by mixing ten parts of sulphide of carbon with one of oil of turpentine, and then adding enough gutta-percha to make a tough, thickly flowing liquid. One essential prerequisite to a thorough union of the parts consists in freedom of the surfaces to be joined from grease. This may be accomplished by laying a cloth upon them and applying a hot iron for a time. The cement is then applied to both pieces, the surfaces brought in contact, and pressure applied until the joint is dry.

A LOCOMOTIVE IN A QUICKSAND.—A locomotive went through a bridge on the Kiowa creek, 42 miles east of Denver, Col., last spring, and instantly disappeared in the quicksand bed of the creek, baffling all attempts to recover it. For the past six months the search for the missing locomotive has been kept up, resulting in success a few days ago, when it was found buried 40 feet deep in the quicksand. The sand had been removed for a great number of yards around the scene of the disappearance of the engine, a hydraulic ram being used, the locomotive being found at last after a search of six months. The instance is one of the most remarkable on record.

ELECTRICAL TEST FOR OILS.—Prof. Palmieri, of Naples, has recently constructed an apparatus which allows the purity of oils to be judged of by the resistance that they offer to the passage of electricity. Olive oil—a poorer conductor than any other—is taken as the standard of comparison. The apparatus may also serve to reveal the presence of cotton in silk fabrics; for a very small proportion of cotton in silk tissues greatly increases the conductivity of the latter.

CELLULOID.—This substance, though prepared by Mr. Hyatt, an American, as long ago as 1869, has only lately been turned to much practical account. It is prepared by subjecting ordinary paper to the action of a mixture of nitric and sulphuric acids; washing this till all trace of acid disappears; drying the product, powdering the same, and mixing it with camphor; drying and repeatedly pressing this mixture, at last applying heat, when the celluloid appears in the form of transparent, elastic rods or slabs. As it is hard and not easily broken at ordinary temperatures, susceptible of high polish, and capable of being cut into extremely thin plates, yet elastic, and, at high temperatures, malleable, plastic and even fusible, it has become extensively used in the manufacture of the rims of eye-glasses, cheap ornaments, cigar cases, etc., and, when colored, as a means of imitating ebony, lapis lazuli and malachite. It has also been employed in making elastic belts, trusses, etc., and some of its applications in dentistry were patented as early as the year of its discovery.—*Moniteur des Produits Chim.*

RINSING WINE BOTTLES.—Bottles, after being some time in use, are apt to acquire a crust or coating very difficult to remove by ordinary rinsing. The *Bohmische Bierbrauer* gives the following methods for removing such impurities: 1st, soak them in permanganate of potash; 2d, rinse the bottles out with a solution of equal parts of muriatic acid and water; 3d, chloride of lime and water in the proportion of one ounce of the lime to two pints of water, and allow the bottles to lie in the solution for three or four days; 4th, strong sulphuric acid may be put into the bottles, which may then be corked and allowed to stand for a day or two. This should remove the strongest crust. Either of these four methods requires great care. The chemical should in all cases be carefully rinsed out with clean water, and it should be borne in mind that all acids are extremely injurious to clothes, etc.

CELLULOSE WASHERS.—For the purpose of packing joints which are to be hermetically sealed, as retort-connections, couplings, etc., where vulcanized rubber has usually been used, cellulose appears to be even a better material. It is very cheap, readily absorbs water at first, thereby becoming pliable, and adapts itself more accurately to the surfaces it is intended to make tight. If a joint is exposed to steam, and is to be frequently opened, the cellulose should be soaked in oil.

Good Health.

Milk in Medicine.

Milk and lime-water are now frequently prescribed by physicians in cases of dyspepsia and weakness of the stomach, and in some cases are said to prove beneficial. Many persons who think good bread and milk a great luxury frequently hesitate to eat it, for the reason that milk will not digest readily; sourness of the stomach will often follow. But experience proves that lime-water and milk are not only food and medicine at an early period of life, but also at a later, when, as in the case of infants, the functions of digestion and assimulation have been seriously impaired. A stomach taxed by gluttony, irritated by improper food, inflamed by alcohol, enfeebled by disease, or otherwise unfitted for its duties, will resume its work, and do it energetically, on an exclusive diet of bread and milk and lime-water. A goblet of cow's milk may have four tablespoonfuls of lime-water added to it with good effect. The way to make lime-water is simply to procure a few lumps of unslaked lime, put the lime in a stone jar, add water until the lime is slaked and of about the consistency of thin cream; the lime settles, leaving the pure and clear lime-water at the top. Great care should be taken not to get the lime-water too strong. Keep to the direction as to the consistency, and when the water rises pour it off without obtaining any of the lime.—*Herald of Health.*

ARTIFICIAL MILK.—The *American Journal of Pharmacy* says the best substitute for mother's milk, according to Martiny, is the yolk of a chicken egg, which weighs, on an average, 231 grains, and when diluted with two ounces of water of about 100° and 76 grains of milk sugar, has nearly the same composition as the milk in the first period of lactation. Subsequently, the fat and protein decrease, and to one yolk may be added four ounces of water, and 100 grains of milk sugar.

WEAK EYES.—Bathe in soft water that is sufficiently impregnated with spirits of camphor to be discernible to the smell—teaspoonful of spirits of camphor to tumbler of water. For inflamed eyes use milk and camphor, adding a little more of the camphor than above.—*Herald of Health.*

RAW OYSTERS are more digestible than cooked ones. It is believed by some that there is a true gastric juice in an oyster's stomach, which assists in digesting them. This, however, is not known with certainty.

TURNIPS and carrots contain about 90% of water. Their chief value is as a divisor of more nutritious food, to allow the gastric juice to act on it more readily, and as a relish.

SUGAR.—Is not sugar an objectionable article of food? Ans.—No. Sugar is a carbo-hydrate, and bears a close relationship to fat, only the latter contains about two and a half times as much force-giving quality. It is objected to sugar that it deranges digestion, obstructs the liver, spoils the teeth, and in many ways does harm—no doubt of it. Taken on an empty stomach, and in great quantities, sugar is injurious; but as a part of our food, and used in moderation, sugar is not only harmless but very beneficial. Children should be allowed a reasonable amount of sugar as a part of their meals, but candies, as generally sold, made partly of sugar or glucose, and many poisonous ingredients, should never find their way into the stomachs of our little ones. So, too, the syrups made by the action of sulphuric acid on corn-starch, or the refuse in corn-starch factories, making a beautiful golden-drip syrup, is a very dangerous article, spoiling both stomach and teeth. In using sugar or syrups, choose only the purest and best sorts, otherwise much harm will come from them. As you value teeth, stomach, and health, never use those articles of food manufactured in the chemist's shop; if you do, you must expect to suffer the consequences. Half the ills of life would be avoided by careful attention to the wise choice and adaptation of food to daily needs.—*Dr. Holbrook.*

RAW ONION AS A DIURETIC.—Dr. G. W. Balfour, in the Edinburg *Medical Journal*, records three cases in which much benefit was afforded patients by the eating of raw onions in large quantities. They acted as a diuretic in each instance. Case first was a woman who had suffered from a large white kidney and constriction of the mitral valve of the heart. Her abdomen and legs had been tapped several times, but after using onions as above she had been free from dropsy for two years, although still suffering from albuminuria. Case second suffered from heart disease, cirrhotic liver and dropsy. Case third had dropsy depending on tumor of the liver. In both of them the remedy had been used with good results. Both had been previously tapped, purgatives and diuretics alike having failed to give relief. All other treatment having failed to give relief, recourse was had to the onions. Under their use the amount passed steadily rose from 10 to 15 ounces to 78 or 100.—*Herald of Health.*

PHOSPHORUS A CURE FOR SCIATICA.—It is not ordinarily wise to try remedies for effecting cures which one finds in the newspapers. But where the ingredients are such that no harm can arise from their trial, and the source from which the prescription emanates is likely to be reliable, the afflicted will gladly try almost any remedy recommended. Dr. Volquardsen reports in Schmidt's *Dictionary* and the Pesth *Medico-Chirurg. Presse*, both good authorities, from which the London *Medical Record* copies, a case of sciatica which lasted for two years and defied all treatment. He then arrived at the idea of trying the internal use of phosphorus, which he prescribed in doses of 15 milligrammes (about one-fourth of a grain) three times a day. Three days sufficed to obtain a marked improvement, and three weeks brought a complete cure.

BRAIN POISONED BY TOBACCO.—A peculiar case of metal hallucination has just appeared in Battle Creek, Mich., in the person of a young man about 18 or 20 years old. He is a cigar-maker by trade, and has been in the habit of smoking from 10 to 30 "green" cigars daily. He has not drank liquor sufficient to produce delirium, and yet he is a raving lunatic, and suffers all the horrible phantasmagoria that pertain to the fully developed tremens. He has worked in and used tobacco ever since early boyhood. Of late years he had used it extensively, principally in strong cigars; and it is supposed that the nicotine has so poisoned and shattered his mind as to partly paralyze it, thus producing the disorder. He has been taken to the insane asylum at Kalamazoo for treatment.

DEPRIVATION OF SOLAR LIGHT.—It has been repeatedly claimed that depriving miners of solar light injuriously affects their health. This point has recently engrossed the attention of Dr. Favre at the Commentry collieries. He does not think that the mortality of miners must be attributed to the action of the deprivation of solar light upon the blood, and cites by way of confirmation that he examined the blood of certain of the horses which were kept underground all the year, and he found the normal number of corpuscles in the blood.

REMEDY FOR COLOR BLINDNESS.—*La France Medicale* states that M. Delbeuf has found that if a person afflicted with Daltonism looks through a layer of fuchsine in solution, his infirmity disappears. A practical application of this discovery has been made by M. Joval, by interposing between two glasses a thin layer of gelatine previously tinted with fuchsine. By regarding objects through such a medium all the difficulties of color blindness are said to be corrected.

A MAN WHO BURST.—A German medical journal gives an account of a man who literally burst from taking four plates of potato soup, and many (how many is not stated) cups of tea and milk, followed by a large dose of bicarbonate of soda to aid digestion. His stomach swelled enormously, and tore the diaphragm, causing immediate death.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Walled Lakes; Barnes' Foot-Power Lathe; Machine Shop Rambles; Three More Railroads; Screw Cutting Tools in Sets, 17. The Week; The Silver Producers; The San Francisco Chemical Works; The Annual Bullion Yield, 24. A Curious Water Elevator and Air Compressor; Yokutsian Geology; An Improved Vertical Mining Pump, 25. New Incorporations; A Kingdom for a Process; Bullion Shipments, 28.

ILLUSTRATIONS.—Barnes' Foot-Power Lathe; Elterich's Saw Cutting Tools, 17. Deane's Double Acting Vertical Mining Pump and Engine, 25.

MINING STOCK MARKET.—Sales at the San Francisco, California and Pacific Stock Boards, Notices of Assessments, Meetings and Dividends, 20.

MINING SUMMARY from the various counties of California, Nevada, Arizona, 21-28.

NEWS IN BRIEF on 29 and other pages.

CORRESPONDENCE.—The Search for Refractory Ores; Defects in the Mining Laws; Cost of Artesian Wells; Refractory Ores, 18.

MECHANICAL PROGRESS.—Dry Graphite fo Steam Cylinders; Locomotives Without Fire; A Magic Car; The Age of Steel; Composition of Bronze for Machinery; Preservation of Timber for Mining and Railroad Purposes, 19.

SCIENTIFIC PROGRESS.—An Alleged Dissociation of the Elements; Discovery of a New Mineral, 19.

THE ENGINEER.—The Strength of Locomotive Boilers, 22-23.

USEFUL INFORMATION.—Glass Millstones; To Prevent Rust; Depth of Roots; Cement for Leather; A Locomotive in a Quicksand; Electrical Test for Oils; Celluloid; Rinsing Wine Bottles; Cellulose Washers, 23.

GOOD HEALTH.—Milk in Medicine; Artificial Milk; Weak Eyes; Sugar; Raw Onion as a Diuretic; Phosphorus a Cure for Sciatica; Brain Poisoned by Tobacco; Deprivation of Solar Light; Remedy for Color Blindness; A Man who Burst, 23.

MISCELLANEOUS.—Snake River Again; Our Solar System; Why the Sierra Nevada is Larger than the Coast Range; Buying Gold at Boise, 18. Mines and Works of Alnaden.—No. 17; The Clifton Copper Mines, 22. Boulder County Ore Product for 1878; Silver Cliff; Singular Occurrence; Profit on Coinage; Cost of the Electric Light, 23.

NEW ADVERTISEMENTS.

The Week.

The week has shown us some little promise in the way of rain, hut the envious north wind hlew off the clouds before very much moisture was precipitated. Water is hadly needed everywhere except in the Comstock mines, where they have a surplus they would like to get rid of. Nothing startling has occurred in mining circles during the week just closed, nor have stock circles been at all agitated. S. P. Dewey has issued a pamphlet on the honanza mines of Nevada, in which he claims to expose gross frauds of the management. As far as we can see, from a casual examination of the pamphlet, it relates principally to a quarrel hetween the writer and the honanza firm. It contains, however, some diagrams of the mines, showing sections of ore bodies, etc. A feature of the week we ehould all note with pleasure, as showing our standing as a nation, ie the remarkable success of the funding scheme. In the first five working days of the new year, Secretary Sherman sold $28,000,000 of the 4% honds, a fact unprecedented in the history of funding operations. The banks which have 6% bonds on deposit with the Treasury to secure their circulation, are withdrawing them to sell before the premium drops off, and replacing them with 4% honds. This exchange, which has just commenced with regard to the seriee of 1867, will cause a demand of from $50,000,000 to $100,000,000 of 4% bonds.

The San Francisco Chemical Works.

We have of late frequently called the attention of our readers to some of ths more deserving technical industries which have grown up in our midst, and it is our intention to continue to do so from time to time, as ws helieve that it is to the intsrest of our readers and to the henefit of the coast that we should do so.

In furtherence of this idea we recently paid a visit to the new establishment of the San Francisco Chemical Works, at Berkslsy. These works are owned hy Mr. Eghert Judson, well known to most of our readers as the inventor of the "Judson powder," and hy Mr. J. L. N. Shepard. They were formerly situated in San Francisco, hut as the city extended itself to the suhurhs, it hecams necessary to find a more distant locality for them, and they were very wisely removed to Berkeley. The firm purchased what was formerly an island, ahout a mils north of the Berkeley landing, and is at present separated from the main land hy a low and nearly swampy tract, hut may be approached either hy the sandy heach or hy a good wagon road. These works are upon the shore of the hay, and a good landing is ohtained for sailing vessels hy a wharf which runs out to deep water.

The only products of manufacture at the present time are nitric acid, sulphuric acid and fine sulphur. Muriatic acid can he made at any time when it is called for, although there does not seem to he any very great demand for it on this coast, and the firm have already a quantity on hand sufficient to supply all the dsmand which may he made for a long time. The firm supply the U. S. Mint with the nitric acid for the separation of silver and gold in the bullion which they huy for coinage. The acid for this purpose is required at a strength of only 38° B. (ahout 55% of HNO_3), hut it must he very pure and especially free from chlorine. The sulphuric acid which the mint requires is 63° B. (ahout 82% of H_2SO_4.) Besides this they make stronger sulphuric and nitric acids for the manufacture of nitro-glycerine. The nitric for this purpose runs as high as 49° B. (a little more than 91% of HNO_3), and the sulphuric acid as 66° B. (89% of H_2SO_4).

The Sulphuric Acid

Is manufactured in the usual way by introducing the vapors of hurning sulphur, nitrous fumes and steam into condensing chambers of lead. The total volume of the lead chambers is 150,000 cuhic feet. The vapors after passing through these chambers escape through a coks tower through which water is constantly trickling. The diluted acid is concentrated in lead pans, which are economically heated hy the hurning sulphur, until the vapor of sulphuric acid hegins to be given off, when the now partially concentrated acid is conveyed into a series of large glass retorts which are arranged upon a step-like furnacs, so that ths overflow from one retort may pass into the next succeeding hy the action of gravity alone. The concentrated acid finally flows from the last retort into a cooling apparatus, and finally from this into the reservoirs of lead, from which it is conveyed to the landing in pipes, thus avoiding expense in the handling of material. The fumes from the hoiling acid pass into a special condenser made for the purpose, and are thus also utilized. The sulphur from which this acid is made was formerly ohtained from Japan, it is now ohtained in large quantities and in a state of great purity from Nevada. The acid at present made at the works is, we are informed hy Prof. Rising of the University, of great purity for a commercial article, and contains hardly any traces of arsenic, the usual impurity of sulphuric acid. The method of concentrating the acid in use at these works is a continuous method, and is on this account a great improvement on the old one in use at most places, which necessitates loss of time and lahor hy the intermittent nature of the process. Mr. Judson, during a recent trip to Europe, hought in London at an expense of some $5,000 or $6,000, a platinum etill, made hy a new method, in a solid piece of metal, without any of the usual jointings. By means of this apparatus, which will replace the last two of the retorts of glass, it is expected that a much more rapid concentration will he effected. The present capacity of the works is about 1,400 pounds concentrated eulphuric acid per day.

Fine Sulphur

Is also manufactured from the Nevada sulphur, hy a centrifugal mill, which produces sulphur almost as fine as flour of sulphur. This is largely used for the manufacture of ordinary hlack powder.

The Nitric Acid

Is manufactured from nitrate of sodium from Chile. The nitrate is kiln-dried hy the waste heat of the furnaces, and the sulphuric acid used to set free the nitric acid is of 66° B., and consequently the nitric acid produced is much stronger than would he otherwise the case. Eight iron retorts, holding ahout 1,000 pounds each are used, and the nitric acid vapor from each retort passes first through a series of eight halloons of glass, then through 10 earthenware jars of 35 gallons capacity, and finally through another series of eight glass balloons hefore it passes out into the tall chimney and into the air. The distilled acid is then hoiled until the chlorine is driven off. The nitric acid is not made by a continuous process as is the sulphuric acid, but a charge is run in each retort once in 24 hours. Ths total amount of nitrate of soda used per day is ahout two and a half tons.

The total cost of the entire plant for this manufacture is from $50,000 to $75,000, and including the land and other items represents an investment of nearly $100,000. There are 12 men employed in all. Mr. C. C. Judson is Superintendent.

The Annual Bullion Yield.

John J. Valentine, General Superintendent of Wells, Fargo & Co., has prepared the following annual statement of precious metals produced in the States and Territories west of the Missouri river, including British Columhia, and receipts in San Francisco from the west coast of Mexico during 1878, which shows aggregats products as follows: Gold, $38,956,231; silver, $38,746,391; lead, $3,452,000. Total gross result, $81,154,622—heing less by $17,267,132 than for 1877.

California shows an increase in gold of $2,068,000, but a decrease in silver, etc., of $1,323,000—a net increase of $745,000. Nevada shows a total falling off of $16,398,341; the yield from the Comstock heing only $21,295,043, as against $37,911,710 for 1877; a decrease of $16,616,667 from that locality. The product of Eureka district is $6,981,406, as against $5,676,057 for 1877; an increase of $1,305,349. Montana shows a marked increase, all in silver. Utah a falling of over $2,000,000, hut nearly $1,000,000 of it is caused hy the reduced valuation of silver and lead hullion. Although Colorado shows $1,680,802 less than for 1877, the yield has heen really greater, as reports to us for 1877 duplicated the product of certain localities, hut ths duplication was not discovered soon enough to be corrected in our statement for that year.

Statement of the Amount of Precious Metals Produced in the States and Territories West of the Missouri River During 1878.

STATES AND TERRITORIES.	Gold Dust and Bullion by Express.	Gold Dust and Bullion by other Conveyance.	Silver and Gold Dore Bullion by Express.	Ores and Base Bullion by Freight.	Total—Lead, Silver and Gold.
California	$16,482,389	$394,119	$ 809,481	$ 804,522	$18,920,461
Nevada	1,011,373		28,656,413	6,315,168	35,181,949
Oregon	986,647	302,251			1,213,724
Washington	952,806	100,278	227,231		1,373,311
Idaho	1,503,769	79,983	1,858,638	731,295	3,773,685
Montana	135,135	13,513	2,661,405	3,254,500	6,064,553
Utah	2,511,248	251,124	1,459,375	2,011,000	6,232,747
New Mexico	89,848	17,970	310,760	35,235	453,813
Arizona	199,911	10,911	1,116,006	951,555	2,287,983
Dakota	1,846,504	369,300	1,088,254	410,000	2,215,804
British Columbia	1,253,460				1,253,460
Mexico (West Coast)	90,741				90,741
Totals	$25,430,328	$1,975,399	$37,952,314	$14,740,581	$81,154,622

The hulliou from the Comstock lode contained 45% gold and 55% silver. Of so-called hase hullion from Nevada, 30% was gold, and of the whole product of the State, 35% was gold.

The gross yield for 1878, shown ahove, eegregated, is, approximately, as follows:

Gold, 48%.....	$38,956,231
Silver, 48%.....	38,746,391
Lead, 4%.....	3,452,000
Total.....	$81,154,622

All probahilities now indicate that the yield of gold and silver, from the sources named, for 1879 will not greatly exceed $70,000,000.

Following is the annual net product of lead, silver and gold, from 1870 to 1879, of the States and Territories west of the Missouri river, exclusive of British Columhia and west coast of Mexico:

	Lead.	Silver.	Gold.
1870.....	$1,080,000	$17,320,000	$33,750,000
1871.....	2,100,000	19,280,000	34,398,000
1872.....	2,250,000	19,924,429	33,177,395
1873.....	3,450,000	27,483,302	39,206,558
1874.....	3,800,000	29,699,122	38,466,488
1875.....	5,100,000	31,635,239	39,968,194
1876.....	5,040,000	39,292,924	42,836,935
1877.....	5,085,250	45,840,109	44,880,223
1878.....	3,452,000	37,248,137	37,576,030

The exports of silver during the present year to Japan, China, India, the Straits, etc., have been as follows: From Southampton, $29,000,000; Marseilles and Venice, $1,000,000; San Francisco, $9,000,000. Total, $39,000,000, ae against $105,000,000 from the same placee in 1877.

AN association offering homes in New Mexico, along a line of projected railroad, is attracting eome attention among Washington workingmen.

The Silver Producers.

Resumption of specie payments hy the Government of the United States being an accomplished fact, there is a propriety in asking afresh the question: Does the Government, in its coinage enactments noh (as is alleged) the silvsr producers of a fifth of their hard winnings out of the howels of the sarth? Or is the 20% discount on silver only the dropping of ths value of silver in the market of the world, caused hy over-production?

These are questions of vital interest to every miner and stockholder in our great cordilleran industry. For if it be true that the consumption and demand for silver is actually in excess of its production at the present time, the Gsrman demonetization is to be considsred as an adventitious drawhack to our silver intsrest, which calls plainly for a remedy. Such there must, and is now, within the reach and powsr of our independent specie paying nation.

A margin of one-fifth of the product, it will bs seen, is equivalent to more than ons-half of the net profit, which is thus lost, instead of rewarding the enterprising and ensrgetic silver miner.

For making the coin the United States pookets this fifth to the extent of its rsquirements for coinage. It matters little who gets the rest if the producer is rohbed. Yet of ths vitality of our silver intsrest there could he no hetter evidence than its ahility to hear up, as it has done, against odds. It would have shut down prohably, most of the coppsr, iron and coal mines in the country long ago.

Thsre are powerful conflicting interests represented in trade, banking and niniuy, on the currency question. But the currency question is now a thing of the past. The voice of these conflicting intersats has been heard so loudly and conflictingly through the press that to-day, when resumption is an accomplished fact, the currency question passes into history, leaving upon the minds of ths people something like ths impression of a muddle. It will hs easier, perhaps, to deal with ths silvsr question pure and simple.

One of the prominent questions now before Congress—which met on Tuesday of the past week after its holiday recess—is the "ounce dollar" proposition, a remnant of the currency muddle. Prohahly it will he readily disposed off. It is based upon the assumption that silver is not worth 412½ grains to the dollar of gold, but that it ought to bs worth about 480 grains, hecause 480 grains happens to he an ounce Troy. That, it is claimed, would maks an "honest dollar."

But the market determines what is an honest dollar; and tinkering legislation is not likely to improve its honesty. To have an honest dollar, the Government should make coinags as nearly free as possihls; thershy allowing silver to find its own proper level, in relation to gold. Mr. Valentine's report on the production of gold and silver for ths year 1878, does not hear out the assumption that the amount of the latter is disproportionate to that of gold.

Nor is it likely that the experiencs of the world for many centurics is to he set at naught touching the use of silver as a metal adapted to coinage, and for circulation as currency. Of the $300,000,000 of silver thrown out of circulation by Germauy, only about a fourth now remains unahsorhed after three years' time.

If all unnecessary and artificial restrictione in coinage, on the part of the American Congress were removed, the silver question would prohably soon settle itself; and the silver producers would get what they most assuredly deserve, their full and fair reward for engaging in an industry of the utmost importance to this Western country, and to the nation at large; heset at the same time with other than prejudicial legislation in regard to coinage, and from its peculiar nature calling for the largest enterprise, energy and capital combined.

OUR NEXT DECADE.—Mr. Hittell divides his Hietory of San Francisco into subdivisions embracing the "Indian Era," the "Spanish Era," the "Village Era," the "Golden Era," and the "Silver Era." It may he said that the same suhdivisions apply to the coast at large, in a degree—only substituting "Hudson Bay Era" and "Russian Era," for Oregon and Alaska respectively. On the whole our coast is scarcely heyond the Village Era; hut it is evident now that the *Coming Era* will be an era of towns. These towns will he huilt up hy *Railroads*. Next week we will puhlish an original illustration, showing to the eye at a glance the annual mileage of railroade huilt in this country, for the purpose of showing clearly, along with eome supplementary facts, the coming era of the Pacific cost is an Era of Railroads and city building separate and apart from San Francisco.

REVISITING BODIE.—Jos. Wasson, well known to the readers of this journal in connection with Bodie district during the past year, returne there for the purpose of remaining for two or three months to come. He expects to note developments even more thoroughly than hefore, aud furnish our readers with another series of letters. He is a hard worker—eees things for himself—and his ohservations concerning mining mattere are accordingly truetworthy. He is authorized to act as agent for the PRESS, to receive and receipt for subscriptions, etc.

A Curious Water Elevator and Air Compressor.

Mr. John Patten, of this city, has recently obtained through the MINING AND SCIENTIFIC PRESS Patent Agency a patent on a device for compressing air and raising water. The air is compressed by means of a descending column of water; the water is raised by the action of the air thus compressed. This is by no means a perpetual motion machine, although its working is quite peculiar. The apparatus is divided into sections of two different kinds, one for compressing air and the other for raising water. Several sections of both kinds can be connected together in a series of short, independent compressors and lifts, and put in the form of a siphon, in which case the water will be raised to any desired hight by discharging it a little lower than where it is first taken from, and employing more compression than lifting sections. In this case no water will be used but what is being raised by the apparatus. In localities where there is access of surface water, that can be used in connection with the water that is being raised, the outlet will not have to be below the level of the inlet. The variation will depend on the amount of water used, and how far it descends while being used in the apparatus.

For raising water out of rivers, etc., a certain amount of water will be raised a certain hight, by the descent of an equal amount of water through a greater distance than the ascending column is raised; or by the descending of a greater quantity through a less distance, and so on. No matter what form the apparatus is put in, the compressing sections will be put a certain distance apart, along the descending column of water; and the elevating sections will be put a little less apart, along the ascending column. At each compressing section the water displaces its equal bulk of air, which is conveyed in an air-pipe to the elevating sections, where the air displaces its equal volume of water; *i. e.*, raises it from one section to the section above. The compressed air can be used for running machinery instead of raising water, if desired.

The air compressor consists of two chambers setting side by side, which fill and empty with air and water alternately. They are connected with supply and discharge water pipes at the bottom, and atmospheric air and receiving air pipes at the top. There is a float in each chamber that regulates a set of automatic valves, situated at the bottom of the chambers, which allow one chamber to fill while the other is emptying, and as soon as one gets full and the other empty, they instantly reverse, causing the full one to empty and the empty one to fill, and *vice versa*. At the top of the chambers is a set of ingress and egress valves (check valves). While one chamber is emptying, an ingress valve opens, which allows the chamber to fill with atmospheric air. When the action is reversed, and the chamber begins to fill with water, the ingress valve closes and allows no air to escape into the atmosphere. When the air is compressed up to a pressure equal to the hight of the column of water that is filling the chamber, an egress valve opens which connects the receiving air-pipe with the chamber, and as the water fills the chamber the air is displaced and forced into the air pipe, in which it is conveyed to the elevating sections.

The elevating section consists of two chambers, setting side by side, connected with supply and discharge water pipes at the bottom, and supplying air pipe and the atmosphere at the top. There is a set of valves on top of the chambers, which alternately change the compressed air from one chamber to the other; while one chamber is connected with the atmosphere, the other is connected with the compressed air, and *vice versa*. There is a set of ingress and egress valves at the bottom of the chambers, the former connecting with the supply pipe and the latter with the discharge pipe. To illustrate the operation: Suppose one chamber to be filled with water and the other with air, the one that is filled with water to be connected with the compressed air and the other with the atmosphere; suppose the air to have a pressure of 50 pounds per square inch; this pressure on the surface of the water will force it downward through the egress valve, at the bottom, into the discharge pipe, in which it will be raised to a hight of 100 feet. While the air is thus forcing the water out of one chamber, the other will be filling from the supply pipe; as soon as one gets full and the other empty, the air valves instantly reverse, causing the same operation as just described. When the air has the above-mentioned pressure and the water is to be elevated to any very great hight, the elevating sections will occur once in every 100 feet; if the pressure is less, they will occur oftener, the discharge pipe of one, forming the supply pipe of the one just above it.

Persons desirous of obtaining further information on this subject, can address or call on the inventor, Mr. John Patten, 18 and 20 Fremont street, San Francisco.

THE Post Office department has redneed the prices of stamped envelopes on an average 20%, the effect of which has been to largely increase the requisitions for the same.

CORK refused to receive Gen. Grant.

Yokutsian Geology.

The legends of all nations are verbal classics which often contain the substance of close observation and intimate acquaintance with nature's phenomena. In the guise they are the aboriginal forms of science, without any separating line between the known and the unknown. The aboriginal, the infantile, and the uncultured mind alike find recourse and pleasure in a solution of fancy. Theory is interwoven with natual phenomena in a plausible way.

"Why the Sierra Novada is Larger than the Coast Range," on our inside pages, is an amusing example of the manner in which our California valley Indians have bridged, with this ancient and time-honored bridge of fancy, a gap like the Yosemito valley which they found between the known and the unknown. All the aboriginal nations have personified, in this manner, the mystery of the Great First Cause, and the origin of evil. Many of them deify the perfect man. For a people to have heroes and not to worship them, argues, indeed, a degree of stolidity and a lack of the capacity to appreciate adequately what is lofty and grand in character.

Many are the pretty conceits of the Greeks accounting for the origin of the earth, and the heavens, and the waters around and under the earth. They were the results of the observation and thoughtfulness of ancient philosophers intimate with nature. She led on to an abyss of darkness, and the poetic mind bridged it with a love story.

Until the geologists, or the poets of the day, give us a better reason for the dominance of the Sierra over the Coast mountains, the Yokutsian philosophy will hold.

AN Annual "Mining Summary" for the Pacific States and Territories, during the year 1878, will be published in the MINING PRESS shortly. There are not many persons in a position to realize what progress is really made in this vast region.

BY the time the Oriental mill, recently purchased by the Deadwood mining company, of Nevada county, is ready to commence work, the lessees will have a crushing of from 125 to 150 tons ready, which, judging from past yields, should go as high as $40 per ton.

JUAN MONCASI would-be assassin of the Spanish king, has been executed.

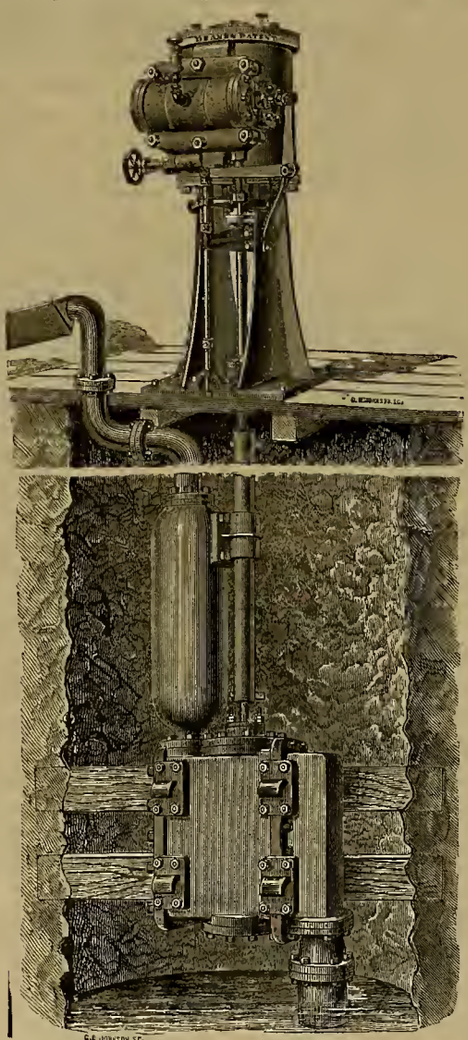
An Improved Vertical Mining Pump.

Among the great variety of Deans's patent steam pumping machinery for mining and other puposes, kept in stock by Messrs. Parke & Lacy, agents for mining machinery, No. 417 Market street, in this city, is the vertical mining engine and pump, shown in the accompanying engraving. This machine is unequaled for many situations where water is to be taken from deep wells or from contracted shafts.

The engine is usually placed over the mouth of the well or shaft, where it can be conveniently oiled and tended, and is connected with the pump at the bottom by a properly guided rod. But one pipe is necessary in the shaft—that for discharging water.

By a patented arrangement, the up stroke and down stroke, through the whole length, can be regulated with valves, which control the motion of the steam piston, but *not* by simply closing the ports, and compelling the engine to work against back pressure.

These machines are made with any diameter of cylinders, from the smallest to the largest, and with any desired length of stroke. The water valves and passages are easily accessible. These pumps work well when submerged. The engraving represents this double acting vertical pump and engine, 16-inch steam cylinder, 10-inch water cylinder, and 24-inch stroke. A great variety of these steam pumps are made, which we shall take occasion to illustrate from time to time. Any order can be filled by Parke & Lacy at short notice.



DEANE'S DOUBLE ACTING VERTICAL MINING PUMP AND ENGINE.

METEOROLOGICAL SUMMARY FOR DECEMBER.—The report of the U. S. Signal Service officer, of San Francisco, for the month of December, is summarized as follows: The mean hight of barometer for the month was 30.118; mean temperature, 51.6°; mean humidity, 59.4; prevailing winds, north; highest barometer, 30.477; lowest, 29.723; highest temperature, 68°; lowest, 40°; monthly range, 28°; greatest velocity of wind, 40 miles per hour; total number of miles traveled by wind, 5,529; total rainfall, .58 inches. Rainfall in December during former years: 1871, 14.36 inches; 1872, 5.95 inches; 1873, 4.72 inches; 1874, .33 inches; 1875, 4.15 inches; 1876, .00 inches; 1877, 2.66.

THE New York *Sun* speaks of the Sandwich Islands as having leaped, in the last half century, from barbarism to civilization. Queen Emma presents a greater advance over Kamehameha II. than Queen Victoria over William the Conquerer.

Academy of Sciences.

On the 6th inst. the annual election of the officers of the Academy took place. There was but one ticket in the field. All the old officers were re-elected, with the exception of Corresponding Secretary, in which position S. B. Christy succeeds A. B. Stout. The officers are: President, George Davidson; First Vice-President, H. W. Harkness; Second Vice-President, Henry C. Hyde; Recording Secretary, Charles G. Yale; Corresponding Secretary, S. B. Christy; Treasurer, Elisha Brooks; Librarian, Chas. Troyer; Director of Museum, W. G. W. Harford. Trustees—Wm. Ashburner, R. E. C. Stearns, Ralph C. Harrison, Geo. E. Gray, Thomas P. Madden, John F. Miller, B. B. Redding.

In the evening the annual meeting was held. It was well attended. The President, George Davidson, occupied the chair.

Mr. Ashburner chairman of the Board of Trustees, submitted a report, in which, after reviewing the sources of the finances and some other things, he took up the subject of

The James Lick Trust,

And said: "In March last the Judge of the Nineteenth District Court rendered a decision against the Academy in the suit pending against the Lick Trustees. An appeal has been taken in the Supreme Court, and the case is now set for hearing on the 16th inst., and so I confidently expect a speedy settlement of this question. A great deal of obloquy has been heaped upon your Board for the position it has taken in this matter, and the Trustees have been accused of throwing impediments in the way of an execution of an important trust, in which all the people of the State, and perhaps the world, are greatly interested. I trust you will all believe me when I assure you that this Board, under the guidance of its late President, has never been actuated by a spirit of captious opposition, but has always been united as one man in what we considered due to the Academy and ourselves as Trustees of its property. When the suggestion of a compromise was first made, we immediately recognized the propriety of such a step, and assisted in its being carried out, so far as lay in our power. But we did not consider it consistent with our duties as Trustees to relinquish on behalf of the Academy of Sciences a contingent interest in a property which we all hope will one day prove very valuable, without being authorized to do so by the Courts. The question at issue, therefore, is not whether a compromise shall be made, for this has already been asseuted to, but whether the money to effect this shall be paid out of the residuum of the estate after paying all other bequests, and in which the Academy jointly with the Society of Pioneers is interested, or by a pro rata upon the beneficiaries."

The Finances.

The Secretary reported as follows: Receipts for the year, $8,668.35; disbursements up to December 31st, $7,171.73; balance on hand, $1,496.62, with two or three bills unpaid. However, since the opening of the year, the society has been compelled to borrow money for several purposes, especially to square up a very heavy tax bill; so that the society is really in debt $3,027.

The President's Report.

President George Davidson, spoke of the effect of the hard times on the finances of the society. Notwithstanding, the ardor of the members had in no degree cooled. He referred with pleasure to the spirit of unanimity that had prevailed in all departments during the year. He hailed with satisfaction the advent of many new and energetic members. He spoke favorably of the action of the trustees in relation to the Lick Trust. All were waiting quietly for the legal settlement of the questions at issue; and meanwhile did not come before the public in discussions that could be of no avail. He spoke most feelingly of the late D. D. Colton, whose energy, sagacity and generosity, he so well knew from contact with him in the affairs of the society. Like reference was made to the late William Rulofson.

B. B. Redding presented an interesting paper on the "Foothills of the Sierra Nevada," which we shall publish next week.

Dr. Herman Baer was elected a life member as a recognition of his valuable services to the Academy.

A vote of thanks was given to the Secretary, Charles G. Yale, who has for several years faithfully performed the duties appertaining to that office, as well as those of Secretary of the Trustees and Council, without any compensation. S. R. Throckmorton, Edward Bosqui and Louis Sloss, were appointed a committee to audit the accounts of the society.

DR. HOLDSWORTH has rich claims at Milton on the ridge 17 miles east of Forest City, and seven miles south of the Buttes and on the boundary lines of Nevada and Sierra counties. He has gravel claims and rock bearing gold, silver, and copper. The description of the claims in the Nevada City *Transcript* makes the Doctor look like a veritable Crœsus.

DURING the past six years the Bald Mountain Company, Sierra county, has paid dividends to the amount of $664,000, which is $110,666 per year. Gold to the amount of $1,300,000 has been taken from the mine in that time.

DEWEY & CO.

American & Foreign Patent Agents

OFFICE, 202 SANSOME St., N.E.Cor. PINE, S. F.

PATENTS obtained promptly; Caveats filed expeditionsly; Patent Reissues taken out Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported hy Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; Every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure, with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Baden, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurtemburg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Granada, Chile, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established.

Our schedule price for obtaining foreign patents, in all cases, will always he as low, and in some instances lower, than those of any other responsible agency.

We *can and do* get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country) SOONER than any other agents.

The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more correctly judge of the value and patentability of inventions discovered here than any other agents.

Situated so remote from the seat of government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for pateuts can rest assured that their communications and business transactions will be held strictly confidential hy us. Circnlars free.

Home Counsel.

Our long experience in obtaining patents for Inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing to them the same thing already covered hy a patent. We are always free to advise applicants of any knowledge we have of previous applicants which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents or purchasers of patented articles, can often receive advice of importance to them from a short call at our office.

Remittances of money, made by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money, hut their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency.

Engravings.

We have superior artists in our own office, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

Patents for Mining and Farming Lands.

Having complete arrangements with competent and reliable parties in Washington City, by which we are able to secure prompt and careful attention to law business there, we are prepared to assist Mill and Mine, Canal and Ditch owners in securing patents for their lands, mines and claims, in addition to our general line of patent business.

Many who are acquainted with the manner in which this business has heretofore been conducted, (with or without assistance by local attorneys), will see at once the great advantage of patronizing an establishment that is thoroughly organized and has its representatives in Washington to look after and prosecute their applications before the Commissioner of the General Land Office. The business on this Coast will be atteuded to personally hy a member of our firm, and satisfaction will be given in all respects.

Correspondence from persons desirons of securing patents for Lands, Mines, Mill Sites, Canal and Ditch property, promptly attended to.

Applicants for patents for mining and farming land, whose claims have been delayed for any reason, will find it to their advantage to consult with us and in case of necessity secure the services of our home and Washington branch agency.

DEWEY & CO.,

DEFLECTORS,

Or Perkins vs. Hoskin.

H. C. PERKINS has for nearly two years been threatening orally and through the Press to prosecute all persons using my Patent Deflecting Nozzle, but for *good reasons*, has failed to come to time. I want miners to understand that Deflectors are still manufactured and sold, and that I will defend all suits and assume all responsibility. Mr. P. will confer a favor if he will carry out his threat, as it will afford me the opportunity I desire to again try the case, and he can rest assured that *professional dodges* will not again be allowed to *temporarily* thwart the ends of justice.

I feel confident that the Supreme Court of the United States will ultimately decide in my favor. The superiority of my invention is shown by the means which Mr. P has resorted to in trying to stop my sales. Mr. P. has so degraded himself as to circulate statements which he knows to be *false and malicious*. Notwithstanding the great number of my Deflectors in use, I have heard of but one accident, and this was caused by the breaking of the iron lever from a defect in the material and great carelessness in use. This circumstance Mr. P. has magnified into several deaths and numerous accidents. I refer to the following owners and Managers for testimonials as to safety and efficiency. Some of them have used and discarded Mr. Perkins' device in favor of my much superior one. Messrs. Gould, Gold Run, using 4; Spaulding, Dutch Flat, on different mines, 12; Stone, Gold Run, 2; Morgan, Little York, 6. Bisbee, Iowa Hill, 2; Briere & Wheeler, Bath, 2; McGillivry, Forest Hill, 4; Atkins, Weaverville, 2. I could mention scores of others, but these are sufficient.

Mr. Perkins' device is an infringement on a patent owned by Mr. Craig, who is about to institute legal proceedings to protect his rights. Miners are advised to stand from under. A word to the wise is sufficient. R. HOSKIN,

Manufacturer of Machines for Hydraulic Mining. Address, No. 29 Garden Street, San Francisco, or Empire Foundry, Marysville, Cal.

CAUTION

To Hydraulic Miners.

The public generally and Hydraulic Miners especially are hereby notified that any parties making or using the contrivance known as the HOSKIN DEFLECTOR will be prosecuted to the full extent of the law, said machine having been declared by the U. S. Circuit Court an infringement upon my patent, the

Bloomfield Deflecting Nozzle.

The public are also cautioned against using the Hoskin Deflector because of its danger to life and limb, this device having already occasioned several deaths and other serious accidents. The BLOOMFIELD DEFLECTOR is entirely safe, its two and a half years use without accident, as well as its construction, proves it to be a reliable contrivance.

Any parties wishing to purchase the right to use these Deflectors can do so by applying to the undersigned,

HENRY C. PERKINS,

North Bloomfield, Nevada Co., Cal., October 1st, 1878.

South Pacific Coast Railroad.

New Route (Narrow-Gauge.)

Commencing Monday, September 30th, 1878, boats and trains will leave San Francisco daily from the New Ferry Landing, foot of Market street, at 8:30 A. M., 9:30 A. M., and 4:00 P. M. for ALAMEDA, SAN JOSE, LOS GATOS, ALMA, and all way stations.

Stages connect with 9:00 A. M. train at Alma for Santa Cruz.

EXCURSION TICKETS will be sold Saturday afternoons and Sunday mornings from San Francisco and Alameda to San Jose, Los Gatos, and Congress Springs, and return, at reduced rates, good only until Monday evening following date of purchase.

FERRIES AND LOCAL TRAINS, DAILY.

From San Francisco.—5:30, †6:40, 9:00, 10:30 A. M.; 1:30, 4:00, 5:15, 6:30 P. M.

From High Street, Alameda.—†5:40, 7:40, 9:04 A. M.; 12 M.; 2:40, 4:00, 5:16, 6:24 P. M.

†Daily, Sunday excepted.

The Company are prepared to carry vehicles of all kinds on the Ferry, to and from San Francisco, Alameda and Oakland.

Messrs. Dewey & Co.—*Gentlemen:* I received the Letters Patent for my invention on the 5th inst., and beg to thank you for the gentlemanly and business-like manner in which you have dealt with me from the beginning of my application. I shall always feel it a pleasure to recommend you to all I come in contact with who need Letters Patent. Respectfully, Wm. Dals.

Ingersoll Rock Drills.

In use in the largest and best Mines of the Coast.

HAS AUTOMATIC FEED.

Has less Repairs.

Is Lighter and more Easily Adjusted than any other Drill.

Our DRY AIR COMPRESSORS are the most Economical Compressors in the Market.

MINERS' HORSE-POWER.

This Power is especially adapted to working mines, hoisting coal or building material, etc. It will do the work of a Steam Engine with one-tenth the expense. One Horse can easily hoist over 1,000 pounds at a depth of 500 feet.

The Power is mainly built of wrought iron, and cannot be affected by exposure. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

REYNOLDS, RIX & CO., 18 & 20 Fremont St., San Francisco.

RUSSELL'S AMALGAMATOR.

Patented June 25th, 1878.

SAVE YOUR GOLD

And Also SAVE YOUR QUICKSILVER.

The above Washer and Amalgamator with new patent Wire Bridge Quicksilver Boxes attached, can be worked wet or dry, either by hand, steam, horse or water power, and is easily taken apart and packed. For washing Pulp, Earth, Gravel, Mill Tailings or Black Sand, it is without a rival.

Has been Thoroughly Tested and given Complete Satisfaction.

The entire Lining, Hanging Plates, Riffles and Boxes Amalgamated

IS GUARANTEED TO SAVE THE FINEST OR FLOAT GOLD.

Capacity, 30 to 60 tons per day, according to size. For further particulars apply to

Continued from page 21.

pletion. Repairing and retimbering and enlarging ths main south drift on the 1700 level is making the best of progress. Work is being pushed with great energy at all points.

SAVAGE.—The joint Hale & Norcross east drift, on the 2000 level, will complete a connection with the Chollar-Combination shaft in two or three days more.

SOLID SILVER.—The drift west from the winze below the main tunnel or adit level has cut through the east clay of the west ledge, and owing to a heavy seepage of watsr being sncountered, indicating that a strong flow of water might be tapped, it was deemed advisable to suspend further advancement in that direction until better prenarations cau he made for raising the water and sending it out through the tunnel.

MORNING STAR.—The winze below the level of the south drift from the old tunnel is following down the east slope of the ore vein and is now down 44 ft. For several fest the winze has been cutting a fine character of quartz, carrying bunches and spots of rich ore.

SUTRO TUNNEL.—Total length of the south lateral branch, 1186 ft. Only about 200 ft. further will carry it through to the Julia shaft. The ledge formation passed through of late has been of the most favorahle working character, allowing advancement at the rate of about 100 ft. psr week.

BULLION.—The north drift on the 2400 level of the Imperial, which was re-started 80 ft. back from the facs last week, is now steadily advancing in the west country rock on the west side of the vein, the face heing perfectly dry.

NORTH CON. VIRGINIA.—The foundations for the new machinery ars all completed. The railroad track is also completed so that the new machinery can be unloaded as to need no second shipping or handling.

UTAH.—The surface improvements are making good progress. Sinking the main incline below the 1350 level is making the best of headway, the bottom in good blasting ground.

WARD.—The stone foundations are about completed ready for the reception of the new hoisting engines.

YELLOW JACKET.—The new shaft to-day is down 2129 ft.; ground, hard blasting ledge porphyry, but working well, allowing of very good progress being made iu sinking.

UNION CON.—The repairs to the main north drift from the Ophir on the 1600 level are completed.

HALE & NORCROSS.—The progress on the lightning drift on the 2000 level was very materially interfered witb hy the rise of water during the first part of the week, occasioned by the breakage and stoppage of the Savage pumps. The water has, however, been drained.

BEST & BELCHER.—The pumps are kept running to their full capacity at the new shaft, aud the flow of water is yet so steady and strong that but slow progress can be made with the sinking.

MEXICAN.—The main north drift on the 2000 level is making steady progress, the face in somewhat softer ground. During the first part of the week strong indications of water were encountered in the face, and drill holes have been driven ahead to prevent the flooding of the mine should a large body be struck.

GOULD & CURRY.—Sinking the nsw shaft has been very much impeded hy a strong flow of water, which keeps the donkey pumps runniug to their full capacity.

CHOLLAR-COMBINATION SHAFT.—Laying the foundations for the new air compressor is making good progress. The flow of water is still quite strong, amounting to about 80,000 gallons per day.

TROJAN.—The ore stopes recently opened at the top of the upraise on the second station level are opening out finely, the ore being of a good milling quality.

BELCHER.—The south drift on the 2360 level is steadily advaucing, with very favorable prospects. Opening the new station at the 2560 level is making good progress. As soon as the station aud ore chutes are completed, prospecting drifts will be started on that level and sinking the main incline will be resumed.

SILVER HILL.—The east drift on the 1100 level is now in 60 ft., the face in soft vein matter, streaked with good quartz, carrying strong indication of good ore when the maiu ledge is reached.

OVERMAN—Sinking the new shaft is making the best of progress. Sinking the vertical winze bclow the 1600 level is also making good headway; it is now down 18 ft.

CON. IMPERIAL.—The east crosscut from the joiut Alpha winze on the 2400 level is making good headway, the face in vein material.

TEM PAHUTE DISTRICT.

MR. YOUNG informs the Tybo *Sun* that the outlook is especially bright. The Wyandotte is pushing work rapidly in all their mines, uuder the supervision of Mr. G. C. Rohhins of Eureka. A large amount of very high-grade ore has been extracted, and is now lying on the dump. There is ore enough in sight, in the company's mines, to run a 20-stamp mill for a year, and he thinks a mill will shortly he erected to reduce it. About 40 men are in the employ of the company, under the foremanship of Mr. John Killen. George Russell has gone to Philadelphia to uegotiate the sale of some of the mines owned by David Service aud bimself.

LODI DISTRICT.

LODI.—Grantsville *Sun*, Dec. 28: The Lodi mine is situated in Lodi district, about 27 miles from Grantsville. It is owned by J. E. Holman & Co. The company have sunk three shafts on their ledgs, 140, 65 and 45 feet in depth, respectively, all in good ore. They have from 180 to 190 tons of ore on the dump, and can take out from 10 to 15 tons daily, or, in other words, could keep a good sized furnace running. This is ons of the first mines located in the district.

ARIZONA.

TIPTOP.—Arizona *Miner*, Jan. 3: The Tiptop mine, as work progresses, continues to widen and satisfy every person familiar with its history that it is a genuine fissure vein, and will run down even to the very roots of the gigantic mountains in which it is situated. The company's mill keeps steadily at work on ore from the mine, and is turning out on an average $45,000 per month. In fact, all the mine owners in the district who are working their various claims are more than satisfied with their prospects, and entertain none but the most sanguine expectations for the future of their bonanzas.

CROSSCUT.—Jake Marks returned yesterday from Humhug district, where he has a gang of men drifting on the Crosscut mine, on the 100 level, each way from the shaft, along the ledge, which is from six to twelve feet wide. One drift is in about 30 feet, and the other 20. The pay streak at the end of the 30-foot drift is eight feet wide, four feet of which assays $200 to the ton.

BRADSHAW.—C. A. Luke retnrned from a trip to the various mines of Bradshaw yesterday. The Basin mill was ready to run on Gray Eagle ore, but was delayed on account of the pack-train being unahle to deliver the ore on account of deep snow. At the Tiger work is progressing rapidly; the prospect shaft, which is to be sunk 1,000 feet, is going down as fast as the skill and energy of man can devise. At the Oro Bonito everything is fast heing put in shape to commence operations, the new mill heing completed. A great many men are at work on the various ledges, taking out ore and making valuable improvements. Mr. Luke thinks the snow in the mountains averages 16 iuches, although at some places he found it over two feet.

BULLION.—Beach's team loaded to-day at Wells, Fargo & Co.'s office, 7,500 pounds of bullion, recently taken out at the Agua Fria smelter, from Silver Belt ore. The bullion goes to Ehrenberg per team and thence per steamer and rail to San Francisco.

ACCIDENTAL.—The uew shaft on the Accidsntal mine, Lynx creek, is down 25 feet, and a good vein of very rich ore has been found. The arastras are about to start up and reduce the fine ore now being extracted from the mine.

New Incorporations.

FRESNO M. Co.—Intention: To operate in California. Capital, $5,000,000. Directors—H. T. Fairbanks, Oliver Merrill, W. A. Roberts, W. F. Meyers and Isaac Overton.

BLUNDER G. & S. M. Co.—Location: Nevada. Capital, $10,000,000. Directors—R. P. Johnson, George L. Tucker, W. C. Walker, T. A. Talhert aad C. S. Drew.

BALBACH SMELTING AND REFINING CO.—Intention: To operate in any of the States or Territories. Capital, $100,000. Directors—Leopold Balbach, C. F. Kirchner, C. L. Weller, A. J. Bryant, O. A. Chase, J. P. Allen and J. B. Crockett, Jr.

CALIFORNIA RAMIE MACHINE CO.—Object: To manufacture, sell and erect machinery and works for the extraction of fiher from ramie and hemp. Capital stock, $500,000. Directors—Thomas Trefall, Hugh C. Hinman, E. J. Barry, John J. French and Andrew Vance.

SANTA ROSA G., S. & C. M. Co.—Intention: To operate in the Trinidad district, Lower California. Capital, $10,000,000. Trustees—W. B. Stanly, C. H. Bumpus, A. S. Long, C. W. Frost and H. W. Fortune.

VULCAN M. & M. Co.—Capital, $6,000,000. Directors—Charles Holmes, W. H. Smith, G. W. Fisher, Charles W. Fox and Alexander Brown.

WESTERN ELECTRIC LIGHT CO.—Capital, $5,000,000. Managers—M. S. Latham, J. W. Coleman, George Ladd, J. M. Livingstone, S. Steinhart, E. F. Hall and Thomas Bell.

JENNIE JUNE M. Co.—Intention: To operate in Shasta county. Capital, $5,000,000. Directors—H. C. McClure, Alvin Potter, E. C. Locke, F. N. Delaney and F. H. McCormick.

A NEW INDUSTRY.—A company has just been organized in this city for the manufacture and sale of Boswell's fruit drier, cooking and heating apparatus, with an authorized capital of $100,000, about one-third of which, we understand, has been already subscribed. The office of the company is located in Sherman's building, corner Clay and Montgomery streets, where samples of the driers can be seen, and any information relative to the operation of the company may be obtained. Mr. Eugene L. Sullivan, an old and well-known citizen of the State, is at the head of the company, and S. R. Lippincott, Esq., formerly an extensive manufacturer in the Eastern States, is the Secretary.

WE call attention of parties interested to the advertisement in another column, of the Frue concentrator.

STRIKES among English coachmen and shipwrights are reported.

A Kingdom for a Process.

In our last issue we gavs some account of the work done, and the results arrived at in the Excelsior and Enterprise mines at Meadow Lake. We taks first to-day, the

Mohawk and Montreal.

This mine was one of the very few that offered sufficient hopes to the owners to lead them to continue work, even through several severe winters. A shaft was sunk to a depth of 220 feet or more, and a tunnel run to meet it, so that the ore was carried to the mill on cars. Assays made at different times on ore from different parts of the works were as follows: $65 gold; $159.23 gold; $2.83 silver; $176.80 gold; $682 gold. How imperfectly the ore was worked may be judged from the results of a few runs. In August, 1866, 29 tons worked hy Winton's mill yielded something over $800, or $27 per ton; this, however, without the sulphurets, which were estimated at about $35 per ton. In September of the same year, 48 tons yielded $2,233.02, or $46 per ton; $600 of which came from the sulphurets. In November, 28 tons, chlorinized, yielded $677.40, or $24 per ton. In December, 163 tons gave an average yield of $29 per ton. For 1867 we have account of the working of 54 tons (less the sulphurets), which yielded 65.50 ounces of amalgam, containing $1,082.56 gold, and $16.93 silver; total, $1,099, or $20 per ton. In October, 1868, the Mohawk and Montreal mill (the company built two mills, a five-stamp and a ten-stamp—probably the latter is referred to here) crushed 100 tons in seven days and 20 hours. The yield from this was $3,524.49, or $35 per ton. At this time it is said, over 1,000 tons of similar ore was in sight in the mine.

This is sufficient to demonstrate the imperfections of the processes used. The mine seemed to improve as depth was attained, the highest assays given above being from ore taken out at considerable depth. As stated above, two mills were built. There were also erected roasting furnaces, some, we helieve, at the early stage in the development of the mine, and three more as late as 1869. These latter were large enough for a charge of from 20 to 25 tons, and wers erected, it seems, in order to try the

Burns Process,

Or a modification of the same. In this process the ore was first roasted, and then plunged into a chemical bath (composition not stated) until coolsd. The ore was then ready for amalgamation. It was thought that this process would cost about $8 per ton. About ths same time another process, Hartley's, appeared, which was, no doubt, merely a slight modification of the Burns, but which claimed to be much cheapsr. Both have been consigned to the tomh so far as Meadow Lake is concerned. Both aimed hy use of chemicals to prepare the gold for amalgamation.

The history of this mine is then, in brief, as follows: Large quantities of ors assaying from $65 to $700 per ton, yielding on an average $30 or less per ton.

The Green Emigrant.

This mine was a comparatively late discovery, and was thought one of the richest in the district. The assays reached to $1,000 per ton. Above the ore was noticeably free from base material. The ledge was from five to eight feet wide, and was worked to a depth of 65 feet, perhaps deeper. The ore improved with increase of depth. A run of 50 tons from a depth of about ten feet yielded at the rate of $26 psr ton. At this depth the foot wall was covered with a thin black layer rich in copper and gold. The rest of the ledge was white quartz, heavily laden with sulphurets and free gold. Mint returns from a run on Green Emigrant ore showed the yield to be about $27 per ton; 891 fine. A run of 120 tons yielded at the rate of $23 per ton. Other runs reached as high as $30 per ton.

The U. S. Grant.

This was another of the richest mines, one of those few on which work was continued through the winters. The mine was six miles south of the town of Meadow Lake. The company owned a mill, which we find stated as having five stamps of 500 pounds each. The ledgs was 5½ feet wide, and was worked to a depth of at least 100 feet. At the beginning of 1867 the U. S. Grant was considered the most successful of the Meadow Lake mines. Up to January 7th, 1867, the mill had crushed 271 tons of ore, the gross yield of which is stated at $13,398.57, or about $50 per ton. The cost of mining and hauling the ore is put down at $5.50 per ton; of crushing, $3.50 per ton; leaving, it is added, a nice little profit of $40 per ton(?) At some runs, the average yield was from $12 to $30 per ton. However, in other cases, if we can depend on the figures before us, they ran as high as $110 per ton. We have no facts regarding the later history of this mine. We would like to have a fuller account from some of our readers.

Besides these mines that we have mentioned, there were numberless others that were noticed from time to time in the Meadow Lake *Sun*. Considerable work was done upon many of them, in sinking shafts or inclines. Copper veins were found and a company styled the Peacock Copper, Nickel & Cobalt Company was formed, with a capital of $675,000.

Bullion Shipments

Were for a time reported quite regularly. For August, 1866, they were as follows (how complete the reports are we do not know): Mountain Chief, $188; Mohawk & Montreal, $833.60; U. S. Grant, $1,559.40 (?); Gold Run Phœnix, $698; total, $3,279. September shipments (1866): Knickerbocker, $34.10; Mohawk & Montreal, $2,604.66; Enterprise, $1,210; Alhambra, $260; Moscow, $82; Western Company, $76.37; total, $4,367.13. For October, 1866, the shipments were: U. S. Grant, $4,750; Mohawk & Montreal, $1,294; Enterprise, Wisconsin, Gold Run, Eclipss and Empire, together, $630; total; $6,674.

The Processes Tried.

Somewhere in the district an arastra was rigged. The ordinary mill process we have seen utterly failed. The chlorination and superheated steam process had each a trial. Then came the Burns process, which we have described as far as possible. This processs, it was said, obtained from two tons of Wisconsin ore, which otherwise would yield nothing, three and one-fourth ounces, .917 fine, at a cost of $8 per ton. In connection with this process we find the names of Eagleson & Co., Hartley and James Doling. The last-named gentleman asserted that by his method he had taken from the ore never less than $8 per ton, and had obtained as much as $36 per ton; cost of process, $8 per ton. Matman, of Nevada City, we believe tried his hand at the ores. A man named Crail had a plan for working them. The Fryer process was applied. Another (Gleann's) process is described as follows: The ore is first dumped upon a drying hearth or put through a calcining furnace; thence to batteries or pulverizers. The pulp is then put into an oxidizing furnace. From the oxidizing furnace it is raked into an alkaline bath in vats. From ths vats it goes to amalgamators and pulverizers. Mr. G. introduces a compound of his own to bring about amalgamation. He works ore up to 80% of assay, at a cost of $6.64 per ton. This method was talked of as late as November, 1877. We may have made soms errors in names; if so, ws hope we will he corrected.

In ths present year, Willard's furnace, with which many of our readers are doubtless familiar, has been trisd. We have seen it stated somewhere that Willard's furnace, in combination with Gleason's amalgamation, succeeds in saviug 92% of the assay value. Elsewhere we find the following description of the "new process:" "The pulverizing process takes the place of stamps in a stamp mill, and will reduce a ton of ore in one hour to the consistancy of flour. The pulverized ore is then placed in the furnace and is mixed freely with saw dust. The powdered rock becomes intensely heated hy means of ths fires below, the strong air currents and the burning saw dust. All the sulphur, arsenic, antimony and refractory elements are consumed and drivsn away, and when the furnace cools off ths purs gold remains. The gold is so fine and flourery that wet amalgamation cannot be employed. The gold floats away and is lost. The Secor process of dry amalgamation, howsver, gives perfect success." In connection with this description it is announced (on what authority we do not know) that "Mr. Frank Pauson will put up a $50,000 mill at Carlysle early next spring, with four furnaces and two amalgamators."

Bullion Shipments.

Since our last issus shipments of bullion have been as follows:

Northern Belle, Dec., 28th, $4,463.22; Grand Prize, Dec. 30th, $24,000; Leeds, Dec. 24th, $3,662.12; Tybo, Dec, 25th, $3,047.31; Hillside, Dec. 31st, $5,119; Jefferson, Dec. 30th, $1,753.84; Indian Quesn, Dec. 23d, $3,497.17; Alexander, Jan. 3d, $7,811.51; Star, December, $35,743; Oriental Con., December, $9,075; Highbridge, Jan. 3d, $8,546.48; Pioche, for week ending Dec. 28th, $3,545; Manhattan, Jan. 6th, $11,202.16; Con. Virginia, Jan. 4th, $84,865.18; California, Jan. 4th, $143,078.97; Standard, Jan. 1st, $16,962.18; Bodie, Jan. 1st, $12,347.54; Northern Belle, Jan. 1st, $3,008.75; Hillside, Jan. 4th, $5,350; Martin White, Dec. 31st, $5,776.63; Black Jack, Dec. 30th, $7,700; 2d, $5,035; Tybo Con., Dec. 30th, $8,062.

Shipments for week ending Jan. 4th at Salt Lake were $43,369.

Shipments for week ending Dec. 28th, from Silver City, Idaho, were $18,000.

The Silver Reef *Miner* thinks the January shipments from that camp amounted to $125,000.

The Bodie shipments for Decemher were $180,206, of which $102,070 were from the Standard mine, and the halance from the Bodie.

MAKING ARTIFICIAL FELDSPAR CRYSTALS.—Messrs. Foque and Levy, in a communication to the French Academy of Sciences, state that they have been successful in making feldspar crystals artificially—the varieties crystallized being obligoclase, labrador and albite. The process consists in fusing the feldspar in a platinum crucible placed in a Schlœsing furnace, then placing the bntton before a Bunsen hurner, which keeps it for eight hours at a temperature slightly below that of fusion. Under the influence of that sort of annealing the vitreous mass changes in structure and crystallizes with all the details of form of natural minerals.

IN a trial of the electric light in Philadelphia, 24 Brush lights did the work of 2,400 gas jets.

BROOKLYN'S debt has increased $1,235,566 during the year.

News in Brief.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

Cherokee Flat Blue Gravel Company.—Location of principal place of business, San Francisco, California. Location of works, Cherokee Flat, Butte County, California.

Notice is bereby given, that at a meeting of the Board of Directors, held on the 20th day of December, A. D., 1878, an assessment (No. 40) of five cents per share was levied upoo the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of tho Company, 318 Pine street, Room 6, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 28th day of January, 1879, will be delinquent, and advertised for sale at public auction; and unless payment is made before will be sold on Tuesday, the 18th day of February, 1879, to pay tbe delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors. R. N. VAN BRUNT, Secretary.
Office, 318 Pine Street, Room 6, San Francisco California.

Land Purchaser's Association.—Office, No. 318 Montgomery Street, San Francisco, California.

NOTICE -There are delinquent upon the following described stock, on account of assessment (installment No. 43) levied on the 5th day of November, 1878, the several amounts set opposito tho names of the respective shareholders, as follows:

Names.	No. Certificate.	No. Shares.	Amount
Mrs Matilda Stobr	38	1	$4 00
James L Beyea	43	1	4 00
V Chevallier	64	1	4 00
Geo S Dickey	98	1	4 00
W G Koch	178	1	4 00
Asa Fisk	220	1	4 00

And in accordance with law, and an order of tho Board of Directors, made on the 5th day of November, 1878, so many shares of each parcel of said stock as may be necessary, will be sold at public auction, at the office of the Secretary, No. 318 Montgomery street, San Francisco, California, on Saturday, tbe fourth (4th) day of Jaonary, 1879, at the hour of 10 o'clock A. M. of said day, to pay said delinquent assessment thereon, together with costs of advertising and expeoses of the sale.
C. S. WRIGHT, Secretary.

Orion Mining Company.—Location of principal place of business, San Francisco, California. Location of works, Iowa Hill, Placer County, California.

Notice is hereby given, tbat at a meeting of the Board of Directors, held on tbe 12th day of December, 1878, an assessment (No. 4) of twenty-five cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of tho Company, No. 28 Sansome street, San Francisco, California.

Any stock upoo which this assessment shall remain unpaid on the 13th day of January, 1879, will he delinquent, and advertised for sale at public auction; aud unless payment is made before will be sold on Tuesday, the 28th day of January, 1879, to pay tbe delinquent assessment, together witb cost of advertising and expenses of sale. By order of the Board of Directors. P. CONKLIN, Secretary.
Office, No. 28 Sansome St. (up-stairs) San Francisco, Cal.

Summit Mining Company.—Location of Principal place of business, San Francisco, California. Location of works, Mineral Poiut Mining District, Plumas County, Cal.

NOTICE.—There are delinquent upon the following described stock, on account of assessment (No. 6,) levied on the 10th day of November, A. D., 1878, the several amounts set opposite tbe names of tbe respective shareholders, as follows:

Names.	No. Certificate.	No. Shares.	Amt.
Boring, I C	32	1200	$60 00
Bohn, John	150	200	10 00

BUYER —AND— COMMISSION MERCHANT.

The undersigned, after an experience of forty years in the Grocery Business, has opened an office at No 24 CALIFORNIA STREET, corner Drumm, for buying and selling all kinds of Goods. Parties throughout the States and Territories wisbing an Agent in this Market for the transaction of their business, by entrusting the same to me, I can have special rates made, with full guarantee of satisfaction, or no charge for services.

With twenty-five years' experience in this Market, I think I can suit one and all, both as a buyer and seller. All I ask is a trial. I will also bave a Ladies' Department, under the management of a lady of experience and taste, who will fill all orders for your wives and daughters. Orders for this this Department should be endorsed: "For Lady Buyer."

All parties ordering will be required to send funds with order or satisfactory reference. Respectfully,

WHEELER MARTIN,
24 California Street, San Francisco.

MILL and MINING Machinery OF ALL KINDS FOR SALE by BERRY & PLACE

At the Old Stand, Market, head of Front Street, S. F.

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued, wholesale and retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS Office, S. F.

BY GUIDO KUSTEL,
MINING ENGINEER AND METALLURGIST.

Roasting of Gold and Silver Ores, and the Extraction of their respective Metals without Quicksilver. 1870.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore.

It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus.

It is a work of great merit, by an author whose reputation is unsurpassed in bis specialty.

Price, $2.50 coin, postage free.

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867.

This work is unequaled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Millman, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery etc., which alone are of the greatest value. PRICE, $7.50

BY DEWEY & CO., Publishers. SAN FRANCISCO, SATURDAY, JANUARY 18, 1879. VOLUME XXXVIII Number 3.

The Deane Mining Pump.

Notwithstanding the fact that direct-acting pumping machinery for draining mines costs much less than any other style, a prejudice exists against its employment on account of the concussion—so destructive to pipes and connections—that attends the use of improperly designed and constructed machines. This is claimed to be entirely obviated in the Deane mining pump, by applying a simple cushion (first used on these pumps) to the steam cylinder, compelling the piston to stop and start slowly at the end of each stroke, so that the water valves may have time to seat quietly, and cause no shock or jar.

The Deane plunger pumps, recently introduced here by Parke & Lacy, 417 Market street, in this city, have two plungers working in opposite ends of a water cylinder, divided in the center with valves of the most approved construction. They are intended for situations where the gritty nature of the water prevents the use of piston pumps.

Fig. 2 of the accompanying engravings shows one of these plunger mining pumps with 14-inch steam cylinder, 8-inch plunger, and 12-inch stroke.

Fig. 1 shows a Dean pump, piston style, with 12-inch steam cylinder, 7-inch water cylinder, and 12-inch stroke. The piston mining pumps are made from special patterns, and are designed for situations where the water is comparatively free from grit. They are also desirable for temporary work, and for duty where space is limited. They are lighter, more compact, and cost less than plunger pumps of equal capacities. The linings, water valve plates, piston rods, stuffing-boxes, and water piston-heads are of solid composition. The packing is of fibrous rings, or leather cups, as desired. They run without shock or concussion. The working parts are all readily accessible.

A very interesting little pamphlet has been published by the manufacturers of the Deane pumps, comparing in details the four prominent systems, viz.: Cameron, Dean, Blake and Knowles. These pumps are shown by diagrams, and their details of construction and operation compared one with the other. Those interested in pumping machinery for mines, will find it worth their while to send to the agents for this pamphlet, as it contains a great deal of information not readily accessible from other sources. We have only space for the concluding paragraph, which sums up the advantages of the Deane system as follows:

The Deane system is the *simplest;* as the parts peculiar to it are less in number than those of the Cameron, less than one-half those of the Knowles, and about one-third those of the Blake; is the *most positive*, as it has a straight mechanical connection between the main valve and the main piston; is the *most durable*, as the supplemental and the main are both flat side valves; is the *least liable to breakage* from external causes, as it has no complicated valve-gear, and what it has is between the steam and the water cylinder; in a word, it combines the greatest simplicity with the greatest perfection, both in theory and in practice.

Wintery Weather Note.—The Nevada State papers all talk of cold weather and snow. The cold weather of the past few weeks at Nevada City, terminated in a snowfall on the 8th. In the foothills, as usual, delicate fruit trees are less injured than in the valleys.

We have two correspondents in Arizona who will be heard from this week, probably. Although we are favored with occasional correspondence from all the outlying mining regions, our readers in Idaho, Montana, and Utah will hear in mind that their letters are always welcome; and that a paragraph from a reliable correspondent often goes farther than a heavier article. Every good mining district has its problem to solve, and its comparisons to work out, metallurgically and otherwise. The character of the ore deposits should be understood. Specimens to illustrate these can be sent to the University and to the Academy of Sciences by Wells, Fargo & Co.'s express without charge; and any letters sent to us descriptive of such, will receive due attention.

The great suit against the United States for 11,000 square miles of land in Missouri and Texas was decided by the Supreme court adversely to the claimants.

Fictitious Capital Stock.—An effort has been made in the Constitutional Convention at Sacramento, to cut down the fictitious capital stock so often put forward in the incorporations of mining companies, to something like a reasonable limit, by means of a tax, preliminary to filing articles for record. The Convention decided that such a tax would not be likely to prevent any of the real "wild cat" schemes from being brought before the people, whom it was sought to victimize; while it was certain that it would prevent many honest and meritorious companies from organizing, by placing unnecessary impediments in their way. No one can doubt the good intention of the mover, nor fail to see that it is the mining interest itself that suffers most from dishonesty in any form, that may be practiced by mining operators.

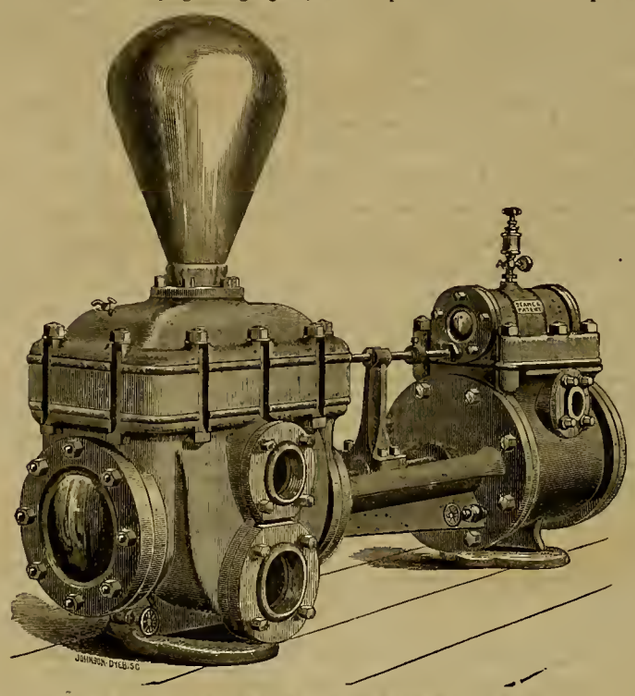

FIG. 1. THE DEANE PISTON MINING PUMP.

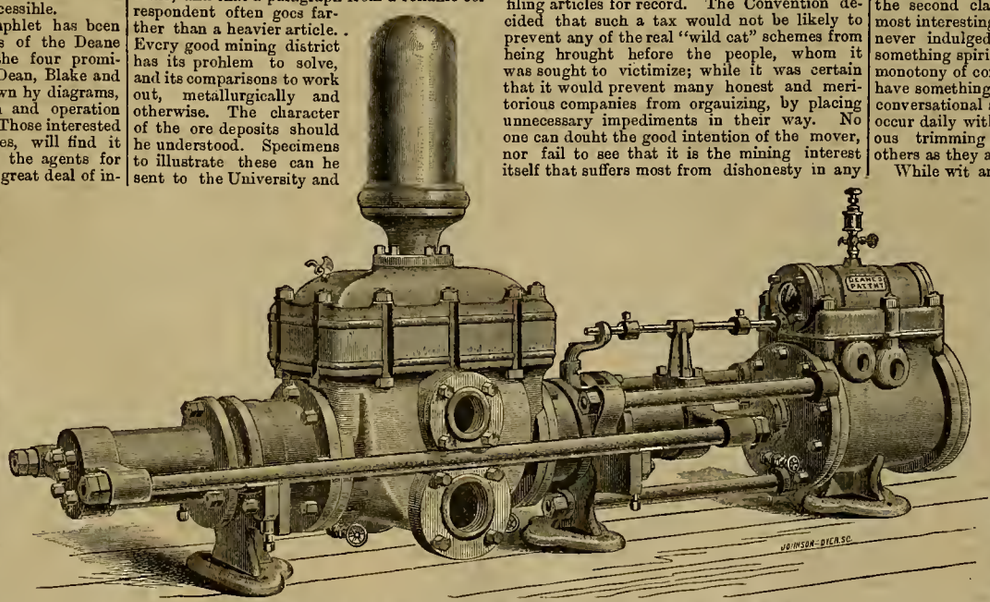

FIG. 2. THE DEANE PLUNGER PUMP FOR MINING PURPOSES.

The Giant Powder Works, half a mile south of Golden Gate Park, blew up on Monday, at two P. M., killing four persons. Loss, $55,000.

A natural mammoth cave has been discovered near Columbia, Tuolumne county.

Practice at the University.

The literary societies of the University at Berkeley conduct a monthly magazine, by electing from amongst themselves successive editors and assistants. The *Berkeleyan* is a portly individual of 63 pages, about one-third advertising matter, printed on the University press. Nothing could be more creditable to the donors of the printing office, and to the University, than such an evidence of vitality, and of a practical literary training. If the young men who are studying at Berkeley can learn, in their four years' course, how to be thoroughly informed on any given subject in practical life; how to write what they know in good enough English for the printer; and how to deliver themselves verbally, in good enough style to be tolerated by an audience of a dozen intelligent persons, they will have acquired the most useful part of the University training. In saying this, it is understood, of course, that the rudiments and the details of physics and the natural sciences, of chemistry and the arts, are a matter of life acquisition, in which the collegian is like the school boy and the man of the world who has never been to school, of course obliged to be "posted," if he would turn his efforts to any account. On the subject of training in the use of the pen, the retiring editor says several things which are the result of his experience, and which are equally applicable to the larger class of students of the world:

"Students are more liberal with their purses than with their literary efforts in sustaining a publication. All want to read, but no one wants to write and be criticised. With all our requests for contributions, we have met with but little return; we were obliged to go directly to the individuals, and to ask for what we wanted. Few articles have been volunteered, and those only were contributed which were read in class, and approved of and recommended, by the Professor of Literature. As a consequence we have received either biographical, metaphysical, or critical articles, and of these the second class predominated. One of the most interesting departments of literature was never indulged in—interesting narratives, or something spirited and light to bridge over the monotony of continuous metaphysics. We must have something light, something amusing. A conversational style would be good. Dialogues occur daily with us, which, with a little judicious trimming and polishing, would amuse others as they amuse us."

While wit and sentiment fill the brighter, yet they are only a small part of the field occupied by writers. Reports of investigations are the simplest form of writing; beginning with the simplest form of a letter. The art or industry requisite, however, in making out a perfect "brief," using the legal term—of covering all the information that is extant or obtainable bearing upon the case—are not often possessed.

The fact that good opportunities are given at the University to persons who may desire to make original investigations in agriculture, chemistry, mineralogy, metallurgy, geology and mechanics; that there are often excellent special topics suggested to be worked up, which have both a practical bearing and interest; that sections of the Academy of Sciences, embracing mining among other branches, microscopical and other societies, have now been organized within reach of the University collections—these are all matters worth noting, in this connection, as it is evident that the University is about to enter upon a more prominent career, in connection with the industrial and scientific progress of the coast.

Jay Cooke, the ex-banker, is in Utah.

Scenes in the High Sierra Back of Yosemite—Continued.

[Written for the PRESS by J. G. LEMMON.]

Glaciers and their Work.

Nowhers slse in California are glaciers more fully represented than here around the hases of this Lyell group of half a dozen peaks. It is not so surprising that the much loftier Whitney group to the south, nor the great domes of Dana and Gihhs northward, scarcsly retain an active glacier, when ws consider the character of their rock, reddish porphyry, greenstone and slates, all good ahsorhants of solar rays. The cold, gray granite and silvery quartz of Lyell, added to the interior location of the group, condense the moisture out of the over-blowing winds for a longer period of the year, to fall in copious showers of snow on their platsaus, thsn to crystallize to *neve*, soon hardening to fields of ice, called *Mers de Glace*, from whence glaciers emerge, grinding their way to the plain.

Firet the Facts, Then their Origin.

These *Mers de Glace* are rihhed from upper to lower side with hard snow, the lowest end the largest hetween each ridge, in the warmest hours of eummer days, there flows the daily melt of snow, filling the cracks that occur always in a mass of ice upon every change of temperature. Down each canyon of every peak, where favored hy shade, flows a frozen river, a glacier. On its back, regularly distrihuted, are rocks of all sizes, some partly covered with the ridges of snow. These glaciers move slowly down the canyons, which they exactly fill, to the level of the melting point at the present time in this region, at an elevation of ahout 11,500 feet. Arrived at the melting line the glacier ahruptly terminates in a sheer precipice, semi-circular in outline. Off from its edge, one after another, fall the rock passengers, forming a curved row of high-piled rocks, a moraine. These moraines are often one to two miles long in their sweeping curve and 50 feet high.

Following down the ravine, it is found to he smooth on the hottom and sides, with no sharp angles in its course, nor yet the short hends peculiar to water courses. At intervals, deep, round or oval lakes are found in or near the center of the ravine.

At every change of level, that is, every precipice down which this ravine-maker continues, just over the hrow there is found a moraine.

Farther on, when the plain is reached, the ravine joins with others to form a deep, narrow valley, strangely regular in contour, no sharp angles or hends, hut at a few points curving gracefully from side to eide, alwaye hending *away* from a trihutary, never *towards* one, as often do rivers.

The Glacio-Aqueous Epoch.

Before we attempt to interpret these phenomena, let us recall the glacio-aqueous epoch of the world's history, aud note the configuration given to our glohe hy the universal ice mantle. The waters of the earth then flowed at an elevation far ahove the tops of the present mountains. In the lapse of time, as condensation of the earth'e elements took place, the waters were gradually drawn off into preparing oceans, at the same time ridgee or undulating hilgee of the earth's crust appeared, constitutiug the present mountain chains, with their complement of material, now removed.

As the sea, with its immcnse blocks of ice, driven ahout hy wind and tide, receded, the icehergs hegan to touch the earth's ribe, and at once the work of grinding and denuding commenced. While age upon age elapsed, lower and lower sank the icy sea, and its ice blocks heat harder and harder upon the rihs. The weakest formed rock gave way first, and, it may he, that hetween now towering peaks there once exieted much higher, hut easier denuded rocks. At length the great icy sea receded until it hecame fenced into basins hy the appearing mountain chains. In the weakest places channels were formed, and as differences of level occnrred, as respects the hasins, the resistance of the sierra harriers caused tremendous pressure upon the sides of these channels, and thc ice hlocke squeezing through, often wrenched the toughest rocks from their ledges and hurled them upon the distant plain. Other rocke suffered the loss of crowns and angles and remain to-day as domes or bosses upon the flanks of the mountains, notably in the region of Yoeemite, where they may he counted hy the score, their scratched and polished eurfaces recording at once the hight, strength, and direction of the ice currents.

At last the glacio-aqueous epoch was ended. The waters were gathered into their future home, the ocean. The dry land appeared, strewn with debris for hundreds and thousands of miles on each eide of the mountain chains, while a warm atmosphere crept from the plains hy degrees up the mountains, clothing them with vegetation.

Next succeeded the wonderful phenomena of

Glaciere.

At first glaciers were developed on a scale so grand as to he scarcely conccived of now. Their work is denuding mountaiu ranges and eharpening domes into pinnacles, as did their parent, the icy sea, hut they toil in a very different manner, slow as the cycles of ages, silent as ths mold of the tomh. Their power is equal to the destruction of the highest mountains of the glohe, and to the furrowing of the despest Yossmites of the plateaus.

It all hegine with the Mers de Glace.

These masses of ice, at first, stranded upon plateaus, afterward formed from snow falling iu favoring localities, are fixed to ths earth, in winter, thoughout their extent, hy freezing. Certain points of greatest cold are dsveloped, coinciding prohahly with the lowest places. At these points the rocks are clasped firmly hy the ics and form a fulcrum for dynamic movements, which will he examined soon.

First, let it he remembered that ics expands when forming, ahout one-ninth of its volume.

Second, when crushsd at a temperature hslow 22° it rs-congeals, over and over again.

Third, that the force of ice-expansion is one of ths most powsrful known, utterly irresistihle.

Now from the point of greatest cold under an ice-field, this fulcrum firmly clasped, the ice expands hy congealing, thawing, crushing and regelation, and pressed in every direction, wrencbing off aud taking the contiguous rocks with it, and rasping them upon those left in the matrix.

The result is a epreading outward and upward of the mass of ice and consequently the excavating of the crater-like amphitheaters that are found, some of them now empty, on the sides of the mountains. This accounts also, for the holes aloug the glacier's track, once ice-womhs now filled with water-forming.

Glaciere at Work.

The upper edge of this powerful excavator impinges against the mountain, undermining rocks and earth, causing them to fall upou its hack, to he carried elowly down the frozen river, as seen.

When glaciers are in operation on hoth sides of a mountain rim, they remove all the material hetween, and thus isolated peaks are formed at the eide.

The greatest amount of pressure will he euccessful in the direction of least resistance, hence the final downward flow of the frozen river.

Glacier Lakes.

The *Modus operandi* of lake-forming is eo interesting that a few words of detail may he apropos. Anywhere that ice forms upon a plateau or mountain side, the work of excavating a hasin may commence, eo soon as the conditions are favorahle, *i, e.*, frequent thawiugs and freezings, which, as shown, are attended hy expansion, crushing of ice and regelation, the latter of course attended with renewed expansion. The fulcrum or fixed point would change from side to side of the hottom seeking the lowest place, from season to season, or rather from age to age. The result would be tbe scooping out of a crater of more or less depth, stopped only hy the condition of unchanged, low temperature reached at the hottom, generally several feet. When a change to warmer temperature occurs (which rise will soon show is sudden, and hy eeveral degrees at once), the ice is melted, and the ice-womh or fountain, hecomes a deep clear glacier lake, or oftcn, if in loose soil easily drained, remains empty.

These lakes distrihuted along a ravine, show where glaciers had their origin, or where portions of a flowing stream fastened on the hottom, for a period, and proceeded to digging wells upon the most gigantic scale, and with the most powerful yet eimple of mechanical agents, ice-expansion.

The warmth of the atmosphere in a distinct stratum at the melting limit, causes an ahrupt termination of the glacier, while its flow heing unhindered in the center, is faster there and causes the outward curve to its front, and this rain-how curve determines the shape of the moraine of rocks dropped from its brow, added to those disgorged from its mouth helow.

The regularity of form of the glacier hed results from the power of ice to remove ohstructions, like an immense furrowiug flow, and its graceful curves *away* from the entering tributary glacier shows hy the degree of deflection the size of the trihutary—a phenomenon never exhihited hy water currents.

Trains of rocks often seen, longitudinally disposed upon a glacier, show the union of two or more such trihutaries. Their rocks deposited upon the terminal moraine form nodules or heaps in the latter. When left *in situ* hy the sudden melting of the glacier, they form medial moraines; while those rocks carried outward to the side of the glacier form the third kind, lateral moraines.

Terminal moraines heing found deposited at the hrow of every precipice in the glacier's course, prove that the heat of the atmosphere has increased hy intervals of several degrees at a time, not gradually—a most important deduction from the study of glaciers, hearing upon the subject of climatology, the eudden withdrawal and introduction of different species of animals, and plants, etc. If the increase of temperature was gradual no terminal moraines of immense size as now seen, would be formed, hut the rocks would he scattered along the track of the receding glacier.

The few rocks found on the hack of a glacier, its very slow movement, the hottom of it only moving in summer, the swiftest recorded motion heing a Swiss glacier that only traveled 4,400 feet in nine years, together with the often, immense hight of the terminal moraines, 50 feet or more, all prove the necessity of vast periods of time required for their formation.

Finally the loug, deep, glacier-carved valleys, like the famous Yosemite, prove the prevalence of glaciers of prodigous size and powsr, plowing ths plateaus of the middle region of the Sierra, down to a low point near the foothills, the melting line heing met at their mouths at an elevation of only about 3,000 or 4,000 fset.

Climate Becoming Warmed.

From this hrief study of glaciers may he deduced a theory of ths positive increass of the earth's atmosphere as the ages have rolled hy; an increase which has advanced the melting point—33° Fah.—up the Sierra, 7,000 or 8,000 fset, since the day of the great glaciers. At that period, such valleys as Sierra and its sisters, now decorating the flanks of the Sierra north and south, were either lakes imprisoned with ice, or complete ice-womhs, the source of glaciers whoss moraines have heen scattered since hy floods from higher basins as their contents were feed; while the great valley of California, and the great basin of Nevada were cold, fresh water seas, their shores harely producing Arctic willows and sages.

At present the warm strata of air are found high up the mountains melting the few, short glaciere away nearly to their founts. When an increase occurs that shall melt them and the *Mers de Glace* all away, and there remaine no more perpetual snow and ice to keep springs and rivere alive in summer; the parched plaine heing mantled hy a torrid substratum of moistureless air, the poor inhahitants of earth, if living hy the same means as we exist now, may sigh for the return of the almost unknown and totally unappreciated hoon—a condition of climate that admits of glaciers.

Mines and Works of Almaden.—No. 18.

FOURTH PART.

Administration and Hietory of the Mines and Worke.

Translated for the PRESS from "ANNALES DES MINES."

I. Administration.

It remains, in order to complete this description of the actual situation of the mines and works of Almaden, to explain the organization of the general administration of the establishment.

The technical direction, or, as they say in Spain, *facultative*, pertains, under the control of the council of mines, to a certain numher, actually of four engineers of the corps of mines. The eldest has the title of director; of the three others, one has charge of the veins San Francisco and San Nicholas, the other of San Pedro y San Diego and also of the workmen, the third of the works, and at the same time the direction of the echool of master-miners at Almaden.

Each engineer has under his orders a certain numher of *capataces* (master-miners). Those of the mine go hy the name of *officiales* and of *ayudantes de mina*. They are suhmitted to a rigorous hierarchy; they come from the corps of timhermen, where they enter after three years study in the school at Almaden. Those of the works go hy the name of *officiales* and *ayudantes de destillacion;* they come from the corps of *auxiliairies de destillacion*, whose duty is the preparation of the charges; the corps of *auxiliaires* is taken from the scholars of the school of master-miners; as the watchmen of the mine, they are alternatively seven daye on duty and seven days at liberty.

The accounts, regulated on the same model as are the other accounts of the State, are confided to an *interventor principal* or *contador*, assisted by a certain number of clerks. A cashier has charge of the money vault.

The chief superior of the mines has the name of *superintendant;* he should he a *brigadier* (that is to say a hrigadier general) of the artillery or engineers. He is supreme judge in technical matters, those of accounts, or of administration; his authorization ie always necessary; he is responsible to the General Direction of the Domain (*Propriedades y Derechos*), which Direction is itself placed under the orders of the Minister of Finance.

The office of superintendent was suppressed in 1871, and replaced hy the institution of a commissary general at the mines of Almaden. This commissary was M. Monasterio. A deplorable riot occasioued—on July 4th, 1874—the assassination of M. Monasterio and that of M. Buceta, engineer of the mines; after thcse tragic occurrences the office of superintendent was re-established October 20tb, 1874.*

The services of the mines and works are performed, some under contract, othere under wages. The work done hy coutract, are, in the mines: the stoping, the huilding of the masonry, the extraction and the introduction, tho transportation intsrior and exterior, the hand pumping, the production of steam for the Watt engine, the repairing of tools, the purchase of wood for timhering, of lims, of sand, of bricks, of coal, of iron, of steel, of charooal, of lumber for carpenters; at the works: the manufacture of aludels, the repairing of furnaces, ths extraction of slag, the furnishing of fuel for the furnaces, the purchase of frascos, of iron, of sand, and of bricks.

The timhering, the distrihution and the care of tools, the charge of steam engines, the work of the shops, the forge, the carpsnter shop at the mine; the charging and discbarging of furnaces, the roasting of ore, the luting of aludels, and of doors, the cleaning of the chambers and aludels, the washing of the soot or cabszas, at the works, are, on the contrary, performed hy contract.

We have already stated hy what means the workmen are ahle to render useless the guaranties which the awarding of the work hy puhlic contract would sesm to offer; we will not return to it.

The following tahle shows the total numhsr of workmen occupied in the different establishments during these last years, and the corresponding produotion. The figures correspond each to a oampaign; the campaign hegine July 1st and fnieh es the 30th of June following:

Years.	At the Mine. Under Ground. Men.	At the Mine. Under Ground. Children.	At the Mine. Above Ground. Men.	At the Mine. Above Ground. Children.	At the Works. Men.	At the Works. Children.	In all.
1870-71	2,287	119	434	179	236	145	3,400
1871-72	2,832	162	494	164	255	158	3,505
1872-73	2,401	147	671	219	267	105	3,816
1873-74	2,031	142	669	213	289	172	3,497
1874-75	2,139	125	647	211	343	235	3,697

Production.

Years.	Ore.	Mercury.
1870-71	14,654.9 tons.	1,185.00 tons.
1871-72	15,527.8 "	1,135.00 "
1872-73	13,509.3 "	1,155.28 "
1873-74	13,714.4 "	976.10 "
1874-75	19,182.6 "	1,264.00 "

The total numher of workmen employed, compared with the figures showing the production, would hc difficult to understand if we did not add eome explanations. There is no one who is occupied in a continuous manner at any one of the establishments of Almaden; according to the kind of duty, the men work one day out of two, or one out of three, or even less; the rest of the time they are occupied with different private works. This eituation ie due in part to a desire to furnish work to the greatest possihle numher of inhahitants; hut it has a much more serious cause which would never permit a different organization.

It is known, in fact, how the mercurial emanations are injurious to the health of those who are exposed to them. They produce first ptyalism (excessive salivation), loosening of the teeth, ulceration of the mouth; then penetrates little hy little the entire organism, and then give rise to a particular tremhling which a long sojourn at the establishment of Almaden does not allow any one to escape. This tremhling is accompanied hy an almost complete loss of powers, and a sad weakening of the intellect.

The intermittance of work allows them to overcome, at least partially, thie mercurial malady; and it is for thie reason, much more than as a consequence of the ideas of inveterate socialists, that the State gives employment at Almaden to a number of workmen much greater than is strictly necessary to the execution of the different works.

The workmen attacked hy the malady have at their disposition a hospital estahlished under excellent conditions. Those whose constitution has hecn strongly attacked hy the malady in consequence of a long sojouru at the mines or at the works, can obtain the concession of a certain amount of land to cultivate in a domain of 7,000 hectares, ealled the domain of Castilseras, which belongs to the estahlishment of Almaden. This domain does not yield anythiug, or scarcely anything, and thc expense of keeping it up increases somewhat the cost of extracting the mercury.

The financial service has heen simplified somewhat since 1870, in consequence of a treaty coucluded hetween the treasurer and the house of Rothschilds.

In order to secure and re-imburse a loan of

Continued on page 38.

*The 4th of July, 1874, should have been the time of renewing the contracts; the engineer, D. Isidro Sebastian Buceta presided at the public meeting for awarding the contracts, when he was suddenly assailed from all sides, and quickly beaten to death. The workmen over-excited to the point of madness ran through the town to find M. Monasterio, who was not able to escape, and was massacred in the middle of the town. He payed with his life for the generous efforts which he had made for the improvement of the mines, of which he had the chief direction. All this was an unfortunate drama, of which the true causes have never been elucidated, and the most guilty authors of which have not been punished for want of proof; politics were no doubt not entirely unconnected with it, and it is to-day believed that this sad riot was fermented by certain socialistic agents, similar to the case of Carthagenia. After these events, the most absolute authority was given to the engineers over the workmen, who have, nevertheless, already retaken great liberties.

MECHANICAL PROGRESS.

A New Direct Process for Making Wrought-Iron and Steel.

We have already made brief reference to some important experiments in the way of a new process for making wrought-iron and steel direct from the ore, which have recently been made under the direction of Mr. Charles M. Du Puy, of Philadelphia. This process is essentially different from all others heretofore either employed or proposed. A full description of the same, with practical results, was given in a paper read by Mr. Du Puy, before the meeting of the Franklin Institute, on the 20th of November last. We regret that we have room for only a brief synopsis of that paper.

This Process Consists

First, in mixing and grinding together in proper proportions the ore, coal, and fluxes. The ground mass is then filled into annular sheet-iron cases or rings without top or bottom. Any desired number of these cases, according to the capacity of the furnaces, are then placed therein side by side, and subjected to the gradually increasing heat of a reverberatory furnace, and in about five hours the ores and their containing cases settle down and become welded into quite compact lumps of iron, which may be removed and welded together, or squeezed and sorted into "muck-bar."

It will be seen from the above that this process is quite the reverse of the blast-furnace method. In that, a tuyere conducts a stream of oxygen into close contact with the ore in the presence of a high heat; while in this, oxygen is excluded, as far as possible—and the moderate heat—from 800° to 1,000° Fah—prevents the combination of phosphorus with the iron. The work is done by reflected heat from the furnace roof. It may be termed a *baking*, instead of a *smelting* process.

Experiments with this Process

Have been made at the Crescent Steel Works, at Pittsburg, Pa., and also in Reading. Over 50 experiments were made at the latter place during the month of August last, with most satisfactory results. Various kinds of ores have been worked—magnetic ore from West Point, ore from New Jersey, Cumberland Valley ore, hematite ore from Newark, besides several others. These ores were worked both separately and combined; were reduced and forged to blooms, and the blooms reheated and drawn out smoothly under the hammer or rolls. Several crucibles of steel were made from the iron and forged into planing tool, which stood all the usual tests.

The iron produced at the Crescent Steel Works was carefully tested in the customary ways to determine the value of iron for high grades of steel. The result showed that it was equal to the most costly grades of Swedish iron. Various fuels were employed in these experiments, and it was shown that good tool steel could be made from iron produced by *anthracite coal dust!*

Further Experiments.

In addition to ores, experiments were made in reducing the scale from rolls—almost pure oxide of iron—which when closely mixed with ground, ore and reduced by anthracite dust forged readily into good bloom. The refuse of iron pyrites, from which the sulphur had been extracted at the New Jersey Chemical Works, and which has hitherto been entirely useless, was also treated with anthracite dust, forged into blooms, reheated, piled with one-third its weight of common muck-bar and plated out well into smooth sheets of No. 26 iron.

Very little labor is required in the process, while the expensive fluxes, such as soda, manganese, etc., are not used at all. A proper mixture of aluminous and calcious ores with lime, to produce a non-flowing glassy slag, was all that was required.

The Economy of the Process.

These experiments prove that good steel can be produced by the De Puy process from iron deoxidized either with charcoal, anthracite-dust or coke-dust. Thus the very cheapest of fuels can be used. It should also be stated that all the experiments were conducted with ordinary furnaces, and such as were not specially adapted to the work; but rather with many inconveniences and unsuitable conditions.

A suitable furnace for the work, from which half a ton of blooms may be produced every 24 hours, need not cost in Pittsburg over $1,000. Only a little lime in combination with waste coal slack—charcoal, anthracite or coke—furnishes all the accessories required. The most common No. 26 iron is also sufficient for the cases. Two men in 10 hours with a 15-horse power engine, will grind and mix and fill the cases for seven tons of blooms. The furnace work is confined to charging and discharging and firing—there being no necessity for manipulating the metal from the time it is charged in the furnace until it is brought to the hammer or squeezer.

It is claimed as proven by the experiments—several hundred of which have been made upon a working scale—that in favorable localities, as in Pennsylvania, where ores can be laid down for $3 per ton, and anthracite fuel obtained comparatively low, blooms, nearly freed from phosphoras, can be manufactured for from $18 to $20 per ton, equally as good as those now produced at a cost of $38 to $50 per ton.

The facts given above appear to be put forth on the highest authority, and the experiments have been conducted on a working scale, and in the presence of numerous practical parties, well qualified to judge of the facts. Is it not possible that this process may be made available here in California? May it not, with perhaps an increased degree of heat, and superior fluxes and fuel, be made applicable for the reduction of the iron sands which are found in such immense quantities along the shore line of this State? At all events, if the foregoing facts are to be relied upon, this process must introduce an improvement into iron and steel making, such as has not been equalled since the introduction of the Bessemer process.

Repairing Boilers.

The following hints in reference to repairing boilers are taken from the *American Machinist:*

It is commonly noticed in boilers that have seams of rivets exposed to the action of the fire, that after being at work for some time, cracks begin to appear, running from the rivets towards the center of the plate. The cause is that one lap being covered by another, prevents the water from getting to the one nearest the fire; consequently the lap nearest the fire becomes hotter, and expands to a much greater extent than any other part of the plate, and its constant unequal expansion and contraction, as the boiler becomes alternately hot and cold, inevitably results in a crack. These cracks may be temporarily repaired by drilling a hole in the bottom or extremity of them, so that the crack is completely drilled out; and, as a rule, this may be safely done if the crack is not more than three inches long, but if of greater length, do not tamper with it but have the plate cut out, if possible.

If it is not practicable to take the plate out, cut out so large a piece that the seams of the patch shall be as far from the fire as possible. Let it be well borne in mind that, in addition to the two laps causing unequal expansion, the sediment or scale inside the boiler obstinately sticks in between the rivet-heads and under the edge of the lap, from whence it is seldom or never properly removed in cleaning the boiler. After drilling out the end of the crack, countersink the drilled hole, and also the hole in the seam above it; so that when rivets are again put in, they will meet each other, or nearly so. Let the heads of these rivets be as thin as possible, so as not again to retain the heat, or attract or harbor dirt.

Sometimes it will be observed that a crack in the seam is running from hole to hole between the rivets. This is always dangerous, and the cracked plate should be cut out and replaced by a new one as soon as possible. In putting patches on any part of a boiler, never cut a hole out with square corners, like the inside of a picture frame; but cut the holes which are to be covered with a patch, round, or as nearly circular as possible. But it is always better "not to put a patch on," but to cut out the defective plate and put in a new one, thus making the boiler as nearly as possible what it was when new. In putting a new plate in a very old boiler, it is advisable to have it a little thinner than the old plates were when new, say one-sixteenth of an inch. In putting on a new plate arrange it, if possible, so that the caulking shall be done on the new iron; but never place the edge of the laps toward the fire, unless a considerable distance from it.

UTILIZING THE WASTE HEAT OF EXHAUST STEAM.—Mr. James Atkinson, recently described before the American Society of Engineers a new apparatus for utilizing the waste heat of exhaust steam. This apparatus consists of a number of straight tubes screwed into a tube plate, which forms the base of an inclosed cylindrical vessel containing the tubes and the water to be heated. These heating tubes are closed at their upper ends, but are open at the bottom to the exhaust steam, for which a short direct passage is provided. Small circulating tubes draw any air out of the heating tubes which would prevent them being filled with steam. The latent heat of a portion of the exhaust steam is transmitted through the heating tubes to the feed-water which is forced through the heater, and passes into the boiler at a temperature of from 210° to 212°. It is claimed that this heater is perfectly free from back pressure in the engine.

A NEW FEED PUMP.—A pump, which seems to have been working for almost two years successfully, has been described recently by Chiazzari, of the Alta Italia railway. It is used for feeding locomotive boilers with hot water heated to within a few degrees of the boiling point. It consists in bringing the feed-water, in a finely-divided spray, into contact with a portion of the exhaust steam during its passage through the feed-pump, and of an automatic arrangement for shutting off the supply from the tender the moment the regulator is closed, thus preventing the admission of cold water to the boiler.

SCIENTIFIC PROGRESS.

New Alleged Discoveries in Petroleum.

The *Oil and Drug Reporter* has been shown specimens of what were claimed to be *saponified petroleum*. These specimens were shown in different forms—as emulsion, paste and cake. "Upon a close inspection," says the *Reporter*, "they appeared to be perfect specimens of saponification, and we were assured that no oleaginous matter, except petroleum oil, was introduced in their composition. These seemed to be a practical contradiction of the theory that petroleum oil cannot be saponified in the very nature of things. Such has been our impression, not from actual experiment, but based upon the statement of experts, who insist that petroleum can be rendered miscible only, and we know that it has been tested by various parties with great care and persistence. We confess our incredulity in the matter, but it is not safe in these days of discovery to doubt the solution of any scientific problem, and we can only say that we hope the enthusiastic author of this long-sought consummation is not deceiving himself. They are claimed to be applicable, to the purposes of scouring and finishing in textile manufactures; to domestic and toilet articles, and by reason of their antiseptic and healing properties, to medicinal preparations. But this is not all. We are assured by the same gentleman that he had eliminated an aniline black from petroleum, which was at once dense, brilliant and permanent; air and exposure to light serving to intensify and make it more firm. This, too, if it shall be assured, will prove another great achievement in industrial art."

In connection with the above, Maj. Henry Howell, of Sarnia, Canada, claims to have discovered a new process of refining petroleum without the agency of heat. A sample manufactured from American petroleum of 45 gravity is stated to be a very brilliant and white oil of 48 gravity and 122 fire test. The yield from the crude was 93%. But the most extraordinary claim for this process is not merely that the means used are entirely mechanical, but also that there is no production of gasoline or benzine, and the entire product is standard white illuminating oil, superior to the oil refined under old methods. This new process, if what is claimed for it be true, is just precisely what the producers have been looking for. But how the lighter parts of crude petroleum can, by a mere mechanical process, be retained so as to stand a fire test of 122°, is something truly wonderful, and is simply equivalent to a mechanical decomposition of a chemical compound.

WHAT SCIENCE HAS DONE FOR PRODUCTIVE ARTS.—When gas was first made for illuminating purposes, some of the substances produced by the distillation of coal and the purifying of the gas, were considered unmitigated nuisances. But these disagreeable products did not escape the persevering investigations of the chemists, and the results are among the wonderful discoveries of science. A curious illustration of this economical value of the ammoniacal liquor is given in the report of the business of the gas works at Bradford, in England. For 10 years a contractor paid £800 a year for this substance, now a new contract has been made by which the company receives £10,359 per annum for it. Fifty one thousand seven hundred and ninety five dollars is a very pretty sum to receive for an article formerly regarded as having little value. The brilliant colors produced from this liquid makes its great value.—*Paint and Drug Reporter.*

THE THIRD FORM OF CARBON IN STEEL.—Mr. Henry G. Dehrunner, in reply to Mr. Blodgett Britton's letter on the third form of carbon in steel, states that he is led to the belief that the latter's semi-graphitic carbon and his semi-combined form of that element are not identical. The product of the action of nitric acid (1.2 sp. gr.) on an iron carbide containing what he has called the semi-combined modification of carbon, is a black powder, which in no other but the mere physical quality of color resembles graphite, while its entire chemical character is similar to that of combined carbon. It dissolves in nitric acid on heating, and causes steel to harden on being dipped at red heat in water, exactly like combined carbon, from which it only differs by the physical *habitus* of its products on solution of steel in cold nitric acid.

SOLUBILITY OF PHOSPHORUS IN ACETIC ACID.—G. Vulpius reports that, by digesting phosphorous for some time in concentrated acetic acid at a moderate heat, about 1-100th of the weight of the latter is dissolved and kept in solution on cooling. If only a few drops of water are added, however, the solution becomes milky from deposited phosphorus, and when the addition reaches the volume of the solution used, no phosphorus at all will be retained in solution.—*Archiv de Phar.*

SCIENCE IN NATURE.—"Everything," says Hugh Miller, "is writing nature's history, from pebble to planet. The scratches of the rolling rock, the channels of the rivers, the falling rain, the buried fern, the footprint in the snow, and every act of man, inscribes the map of her march. The air is full of sounds, the sky is full of memoranda and signatures which are more or less legible to every intelligent human being."

The Mound Builders' Unit of Measure

Mr. J. W. McGill, who has been making a critical study of the artificial mounds of northeastern Iowa and contiguous parts of Wisconsin and Minnesota, finds considerable evidence of the employment of a unit of measurement in their erection, the possession of which would prove the mound builders to be tolerably advanced toward civilization when they entered the country. In the *American Journal of Science and Arts*, for October, Mr. McGill gives a large number of measurements made by him in one of the most extensive systems of mounds in northeastern Iowa, and arrives at the conviction that the linear unit employed by the builders was simply, or had grown out of, the pace or yard.

The northern limit of the mounds of definite dimensions is not certainly known. Mr. McGill has sought vainly for evidence of the use of measurements in the most northerly of the mounds. His own examinations so far extend only to latitude 43° 30′ N., and there the mounds are of constant or related dimensions. The most northerly of the measured mounds are undoubtedly within Minnesota.

In conclusion Mr. McGill observes that if we assume a slow southerly migration to have taken place in the mound builders, it will explain the evident increase in geometrical knowledge attested by the various works found in passing across the United States from north to south. In the Northwest we find measurements of simple lines, but not of angles or areas. In Ohio, angles were correctly measured, the squares being accurate squares and the circles perfect circles; and areas were measured, as attested by adjoining squares and circles being equal or very nearly equal in area, though there is no satisfactory evidence that the cardinal points were known. In the lower Mississippi regions the cardinal points were known. The gradual modifications in the various arms and implements, and the striking improvements in pottery, together with many other important considerations, lend support to this view.

Peculiar Behavior of Cast Iron.

A peculiar phenomenon has been repeatedly noticed with cast iron long submerged in the sea. A gray, spongy, light mass is formed, which in several cases when brought to the surface ignited spontaneously. Thus, for instance, cast-iron cannon raised after 50 years from a man-of-war sunk near Cariscrona, were reduced one-third to the mass described above. After being exposed to the air for about 15 minutes the cannon became so hot that they could not be touched, and the water with which they were moistened was converted into steam. During a naval battle between the French and the English in the year 1545, an English vessel was sunk off Portsmouth. Three hundred years afterward the bronze ordnance of the man-of-war were raised by divers. In one of them there was a cast-iron ball, which, as soon as it came into contact with the air, was heated almost to redness, and then fell to pieces, which weighed together only 19 pounds, while to judge from its diameter the ball must have weighed originally about 30 pounds. Modern chemical science would find it easy to trace the causes of this phenomenon, while a 100 years ago somewhat violent assumptions were deemed necessary to account for it. Thus a ship's physician has placed the following explanation on record: "It is probable that the cannon were sunk in the heat of battle, and therefore had not sufficient time to cool off." Thus the heat must have remained in suspense for a long time, which may account for its promptness in making itself manifest upon return to the outer world.

THE MICROSCOPICAL STRUCTURE OF SPIEGELEISEN.—An interesting inquiry into the microscopic structure of spiegeleisen, by Herr Martens, appears in the November number of the *Zeitsch. des Ver. Deut. Ing.* He states that spiegeleisen consists of a mechanical mixture of the chemical combination between iron and carbon, and of iron without chemically combined carbon; and he finds that the two constituents of this mixture are placed together regularly, and according to determinable laws, the former constituent crystalling after the rhombic system, the latter after the quadratic system. The individual constituents assume the tempering colors at different rates, and so they can be sharply and distinctly recognized in grindings.

NEW MODE OF DETERMINING MOLECULAR WEIGHT.—In the course of some recent experiments Mr. Naumann has discovered indications of a new method of determination of molecular weight, which is specially applicable to substances which, in the pure state, are not volatile without decomposition. In studying the distillation of liquids, which cannot be mixed with water, by a current of aqueous vapor at constant boiling temperature, he has found that the quantities of two liquids passes in distillation and estimated in molecular weights, are in the same ratio to each other as the tensions of vapor of these liquids measured at the constant temperature at which distillation is effected.

A NEW MODE OF OBTAINING HYDROGEN.—Fire is generally used for producing hydrogen on a large scale; but recently a new method has been suggested by Dr. Kollman of the Berlin School of Mines. He states that the gas can be easily produced and at a lower price from ferromanganese by treating it with sulphuric acid.

Ellion Shipments.

Since our la issue shipments of hullion have been as follow: Raymond &Ely, Jan. 7th, $6,193; Highbridge, Jan. 1(h, $10,055; Grand Prize, Jan. 13th, $23,000; orthern Belle, Jan. 8th, $3,527; Jan. 11th, $5,C4; Standard, Jan. 9th, $14,774; Eagle, Jan. 7th$9,261; Tybo, Jan. 10th, $3,827; total 187 $746,552; Hillside, Jan. 14th, $6,700; MartinVhite, Jan. 8th, $11,070; Star Mine, Jan. 13tl $7,500; Con. Virginia, Jan. $28,000; Leed Jan. 11th, $3,549; Indian Queen, Jan. 6th$4,868.

Mining Share Market.

The mining share market during the past week has been without special features with regard to fluctuations in price. The brokers have, however, had plenty to talk about. In the first place, both "bucket shops," as the public stock exchanges were called, have closed up. We have before referred to these institutions, and it is a matter of congratulation to know they have passed out of existence.

The meetings of California, Con. Virginia and Sierra Nevada, were held this week and the annual reports read. California and Con. Virginia, elected the old officers. Sierra Nevada, elected John Skae (President), C. H. Fish, W. S. Lyle, Geo. Congdon and R. N. Graves, as Trustees. The California mine produced last year $10,949,078, and paid out in dividends, the sum of $7,620,000. The total receipts and expenditures were $11,246,539.

Business is improving somewhat in the boards. The sales of the San Francisco stock board from January 8th to 14th, aggregated $1,480,000.

Our usual weekly summary of news from the Comstock, failed to come to hand this week for some unexplained reason, and we are therefore compelled to go to press without it.

News in Brief.

THERE is about 15 inches of snow at Tahoe City.

SIX United States prisoners escaped from the jail at Prescott, A. T.

THE French government proposes to pardon all Communists, except 400 ringleaders.

WILL S. FENTON, a soldier, was found frozen to death Saturday, near Salt Lake.

THE British ship *Allegiance* has gone ashore at the mouth of the Columbia river.

THE production of pig iron in the United States during 1878 was 2,382,000 tons.

THE Belcher is now claimed to be the deepest mine in America, having a depth of 2,640 feet.

LANDS on Salt river, in Arizona, have been set apart for a reservation of the Pima and Maricopa Indians.

HENRY THOMAS was shot and killed by Jack Epperson, Thursday night, at Geyserville, Sonoma county.

AN accident occurred at the Con. Virginia mine Saturday morning, causing damage to the amount of $10,000.

MADAME ANDERSON has completed her task of walking 2,700 quarter miles in as many quarter hours at Brooklyn, N. Y.

THE Indians White Owl and Quit-Ti-Tumps were executed recently at Pendleton, Or., for the murder of George Coggan.

THE Military Court of Inquiry into the responsibility of Major Reno for the Custer massacre, is in session at Chicago.

A DESPERATE affray has occurred at Piedras Negras, Mexico, in which one Mexican officer was killed and another badly wounded.

AT last accounts, 40 of the Cheyennes who escaped from Fort Robinson had been killed, 15 wounded and 40 to 50 recaptured.

ARRANGEMENTS have been made to extend the Utah Southern Railroad from York to 'Frisco, a distance of 155 miles.

THE first water ever pumped into the Sutro tunnel was sent through Sunday by the pumps at the Chollar-Norcross-Savage shaft.

J. WILLIAMS of Roseburg, while at a party at Looking Glass, lost his speech, and has only been able to converse since, at great intervals.

THE overland stages from Eureka, Humboldt county, to San Francisco, have ceased running for the winter. The mail is now carried on horseback.

ORANGE trees raised in Sacramento from the seed appear to stand cold weather quite well, but those imported from the south have suffered in the loss of their foliage, and present a great contrast to the Sacramento raised trees.

FOLLOWING is a statement of the number of flasks of quicksilver shipped by the several mines named, during the past year: Sulphur Bank mine, 9,448; Great Western mine, 5,027; Napa Consolidated mine 3,050; American mine, 119. The total in pounds is 1,359,940½.

THE track of the Southern Pacific railroad is laid to a point 38 miles east of the Colorado river, and is progressing at the rate of a mile and a half daily. Grading is completed 10 miles beyond the end of the track.

THE NORTH AMERICAN REVIEW.—Friends of good, solid literature will be pleased to hear of the continued prosperity of the veteran publication, the *North American Review*. After 63 years' existence as a quarterly and bi-monthly, the *Review*, with the January number, commenced life anew by becoming a monthly. This change will produce a much greater degree of timeliness in the treatment of topics, and will add largely to the amount of matter presented in a year. The managers state that they have secured as contributors for the coming year the most eminent statesmen, scholars, *literateurs*, and men of science, on both sides of the Atlantic. In addition to articles on political, literary and other themes, the January *Review* contains an essay on the preservation of forests, by Felix L. Oswald, which will be read with interest. The *North American Review* is published by D. Appleton & Co., 551 Broadway, New York.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

ALPINE.

I X L AND EXCHEQUER.—Bodie *Chronicle*, Jan. 4: Lewis Chalmers returned to this town several weeks ago, and now has a boarding house started at the I X L mill, and eight or ten men employed building a bridge across Silver creek, between the I X L and Exchequer, and grading a road and place for building at the mouth of the tunnel just back and a little below the I X L.

TARSHISH.—The Tarshish, at Monitor, will start up again under the name of Colorado No. 2 Gold & Silver mining company, with the following well-known gentlemen as Directors: Judge Theron Reed, of Kern county, B. E. Hunter, Judge Griffith, Treasurer Cronkite and Supervisor Merrill, all of Alpine county. The capital of the new company is $4,000,000, in 40,000 shares.

INYO.

FROM BENTON.—"Saxs," in the Inyo *Independent*, Jan. 4: Mr. J. H. Badger recently returned from San Francisco, where he had made an amicable settlement with the defunct Comanche M. & M. Co., and states that if a settlement can be accomplished with all the creditors that the company will soon resume operations, and Benton will be itself once more. The Diana mill has been crushing some very rich ore from the Laura and Modock mines. The Mammoth M. & M. Co., at Lake district, under the superintendency of Jim Cross, is running the mill to its full capacity, with very satisfactory results and without sorting the ore. Supt. Adams, of the Indian Queen, announces his intention to provide the bullion for another dividend on the first of the coming month, or soon thereafter. Morris Burke lately returned from San Francisco, where he incorporated the East Mammoth mine. Mr. P. W. Bennett was here last week. He and L. E. Tubbs have taken numerous claims and filed many liens for laboring men on the Comanche property, of which they propose to collect 100% on the dollar.

LAKE DISTRICT.—Esmeralda *Herald*, Jan. 4: Several parties are now in town from Lake district, having come in to spend the winter. They report about 40 men employed at and around the Mammoth mine and mill—the latter running day and night.

LORD BYRON.—Parties who have been doing assessment work on the Lord Byron mine, on Last Chance hill, struck some rich rock last Thursday. The shaft of the Lord Byron is down 40 feet, and it was in the bottom the strike was made. Some of the rock shows free gold abundantly.

MONTEREY.

COAL.—Monterey *Californian:* The building of the Carmelo railroad from the coal mine to Strader's landing has been commenced, and its early completion is now an absolute certainty. We were informed recently that another very large and promising vein of coal had been found in the immediate vicinity of the tunnel. Mr. Dougine has entire charge of the company's property, including the building of the railroad. The Mal Paso tunnel, in the Mal Paso canyon, is to be continued for a depth of 2,000 feet, which will be the means of tapping and draining all of the three veins now being worked at the Carmelo coal mine. The tunnel at present worked by the company is also to be connected with the railroad by means of a tramway, which will be 3,700 feet long. The railroad when finished will be a little over four miles in length—a three-foot gauge.

MONO.

BODIE.—Inyo *Independent*, Jan. 4: Prospecting is about suspended for the season, so that the many little wild-cat locations wedged in and around claims of real merit may preserve their reputations for the time being. The new field that will attract attention is in the vicinity of the placer diggings at Dogtown. That point is undoubtedly a break or the tail end of the rich mineral belt of Bodie.

NAPA.

QUICKSILVER.—Cor. Napa *Register*, Jan. 11: The Napa Consolidated mine, better known as the Oat Hill mine, is situated in Napa county about 10 miles southeast of Middletown. Thirty men are employed, 20 of whom are Chinamen. These latter do all the underground work. The minimum product of the mine is 300 flasks of quicksilver per month, 76 lbs each. M. G. Rhodes is the superintendent. The entrance is by a perpendicular shaft. In company with the foreman, Mr. Partrigan, I got into the iron cage, and the steam engine let us down to the 400 level. Good working ore gives about two per cent. of quicksilver. The best sometimes runs as high as 12%. The furnaces and retorts of this mine are not equal to the task of reducing all the ore which might be produced, so a small force of men is employed. The Great Western mine is situated north of Mt. St. Helena, and about three and one-half miles southwest of Middletown. The tunnels are run straight into the side of the mountain, and trains of small cars, each drawn by a horse with a lantern on his breast, carry out the ore 2,200 feet. The tunnels and caverns are here much more capacious, and the temperature lower than the former mine. Two hundred men are employed —180 of them Chinamen. Work never ceases at the mines, but is prosecuted night and day, Sundays and Christmas. The Great Western turns out about 500 flasks of quicksilver per month. The furnaces, retorts and condensers are all of the improved patterns. Two little streams of mercury as large as goose quills come out in jets, representing the result of the entire labor of the mine. It seems ridiculously small, but it counts.

NEVADA.

GRASS VALLEY DISTRICT. — Grass Valley *Union*, Jan. 10: Taken altogether the year 1878 has been a good one for quartz mining in the Grass Valley district. It has witnessed a renewed interest in that character of mining, and during the time several new enterprises have been inaugurated, or old organizations remodeled, that are getting fairly upon their feet as remunerative properties. And during the present year they should pay back to their owners compensation for their investments, as a reward for their pluck and confidence in the resources of the district. A large amount of money was paid out in 1878, in the way of assessments to carry on these enterprises, and principally from our own citizens. Prospecting, which generally succumbs to the rains that saturate the ground, has continued without interruption, and by that means many miners in the district have been enabled to continue regular work, who otherwise would have been compelled to be idle or at best put in but broken time. In consequence of this the custom mills have been kept constantly busy, which is unusual for the winter season. While the elements have thus favored quartz mining, they have been unpropitious to the greater and more important gravel mining interest and for the agriculturists, and make enforced idleness in gravel mining that is discouraging to those whose capital and labor is locked up in such investments; and the winter is now so well advanced that none can hope for a water supply that will give the usual complement of a good season.

IDAHO MINE.—The new shaft, below the 10th level, is now down 132 feet, having been sunk 20 feet during the month. The yield of the mine for December was $64,000, an increase of $7,000 over the previous month. The regular monthly dividend (No. 113) of $7.50 per share, amounting to $23,250, was declared on Monday, payable immediately. This is a large dividend, when taking into consideration the necessary payment of the annual taxes and other large outlays outside of the regular working expenses. With the payment of the above dividend the entire amount of dividends paid by the mine is $2,557,500.

CENTENNIAL.—The 3d or 420 level, is being driven north and south, and opens out finely. Of late the company have been doing considerable dead work, preparing the mine for greater production of rock than heretofore. The tributers of late have been taking out very fine rock, and will make first-class wages.

MT. ZION GRAVEL.—Nevada *Transcript*, Jan. 10: A San Francisco company have recently purchased the Mount Zion gravel claims which have been owned and worked by the "George boys" and others for nearly 20 years past. It is one of the oldest pieces of property in the county, and is situated on the ridge road between Eureka and Bloomfield, about seven or eight miles above the latter place. The claim, which is a very large one, fronts on the South Yuba, and extends back to the center of the ridge. A tunnel 1,800 in length has been run in it by the former owners.

EUREKA GRAVEL.—The Eureka Gravel mining company, at Relief Hill, has been paying dividends for eight years past, the claim being good for from $5 to $16 per day for each man working in it. The proprietors consist of a number of Americans, Germans and Danes. John Hickman, one of the owners, has held the position of foreman ever since pay dirt was first struck.

BLUE BANKS.— Nevada City *Herald*, Jan. 7: W. F. Cummings, the banker at Moore's Flat, brought down $30,000 in gold dust from that place on Sunday last. This was obtained from the clean-ups of the Blue Banks and other claims in the vicinity made last week.

SANTA BARBARA.

LEAD AND SILVER ORE.—Lompoc *Record*, Jan. 4: Considerable excitement prevailed for a time last Thursday morning, over the display of a rich specimen of lead ore, containing a quantity of silver, reported to have been *first* found on the Lompoc rancho by Dr. H. C. Dimock. The locality of the discovery is yet unknown, except to the discoverer. An interview with the Doctor elicited the statement that he first discovered the ore while prospecting with a friend, which he is willing to testify to under oath. He further thinks that this section, to-day, is richer in mines, chrome not excepted, than San Luis. Messrs. Sirrine and Anglin are still working up the Bear creek mines, and we may expect to learn something ere long. Specimens from the Dimock and other mines may be seen at this office.

SHASTA.

COPPER CITY.—The Extra company keep up their lick day and night, and the regularity with which they ship the silver bricks is the best proof of what is being done, also of the ore produced from our mines. At the Potter mine the deeper they sink the larger they find the ledge, which carries its rich ore with most remarkable uniformity from top to bottom of main shaft. This mine has more good ore in sight than the mill can reduce in the next 12 months. At the Bully Hill South or No. 2, they have a five-foot vein of good milling ore, which resembles very closely that of the Potter mine. There are three claims on this one vein for a distance of over 4,000 feet, with ore exactly alike in all of them, showing this vein to be an immense bonanza, with ore enough to run 100 stamps. The Winthrop company are driving their tunnel day and night. They have encountered very hard rock. The new tramway is being pushed along at a lively rate, and will be completed to Bully Hill in a few weeks, when the expense of hauling ore will be reduced nearly $75 per day. It looks very gay to the old residents of Copper City to see a train of cars come spinning down the mountain from Bully Hill to the company's mill.

AFTERTHOUGHT MILL.—Reading *Independent*, Dec. 26: At the Afterthought mill, upon the the success of which everything depends, we had the pleasure of meeting Mr. Campbell, the Superintendent; A. J. Loomis, Dan Feit, who is superintending the construction of the mill, and D. J. O'Harra, the inventor of the process by which the ore is worked. The mill, when completed, will be one of the best and most convenient ever put up in any mine. Their machinery will all be run by water power, which will be a saving of money.

PECK MINE AND COPPER CITY.—In company with Superintendent Campbell and Mr. O'Harra we visited the Peck mine, lately purchased by them from another company. It is located so conveniently to the mill that if the company desire to do so, a chute could be made to carry the ore right into the mill; but for the present they intend to haul the ore, and for that purpose have constructed a fine wagon road. The value of the ore varies, say from almost nothing, in the way of silver and gold, to $40 and even $80 per ton, while that which carries but little in these metals is rich in copper. Practical miners talk about this as an enormous ledge. This mining district is, without a doubt, a continuation of the ore at Copper City, and as the bullion already shipped from the latter place shows that it pays, the mines on North Cow creek must also pay.

SOUTH FORK DISTRICT.—The new mill is in fine running order, with its concentrators, roasters, pans and settlers, all doing their part night and day, and turning out the bullion in good shape, under the constant supervision of Mr. Peck, one of its owners. The latest discovery of the country is giving new life to this whole section: O. Engle is the lucky man; a two-foot ledge widens out to ten feet in thickness a little lower down the hill, and still other fine claims are being opened above this by W. Brummett and others.

NEVADA.

WASHOE DISTRICT.

Our usual weekly summary of Washoe mining news having failed to come to hand, we take the following from the letters of Superintendents, on file in the offices of the respective companies mentioned:

CHOLLAR.—Letter of the 11th says: During the past week we have eased and repaired 28 feet of the C. N. S. shaft. Have timbered 15 feet at north end of 1593 level and finished putting in pipe to convey water to the Sutro tunnel. The pump shaft has been cleaned down and pump work completed, and the pumps are now ready to start up. On Thursday we broke the rope in south hoisting shaft and to-day are putting in new ropes. Shall have everything running again to-night.

OVERMAN.—Letter of the 11th says: During the past week the north crosscut has been extended 28 feet and the north lateral drift 20 feet, and the face is in quartz showing a little metal. The excavation for machinery for vertical winze is about completed, and we will commence putting machinery in place by Monday. The new shaft has been sunk and timbered 30 feet. The ground continues very hard with a little seepage of water.

OPHIR.—Letter of the 11th says: Ship this day five bars of bullion, Nos. 19 to 23, value, $19,459.46.

BEST & BELCHER.—Letter of 12th says: The joint east drift, 1700 level was advanced 58 feet during the week, and is now in 300 feet from the lateral drift. Joint east crosscut 1900 level was run 26 feet through hard porphyry, and the vertical winze from this drift sunk 10 feet. At the Osbiston shaft there has been much trouble with water, so that only 15 feet was sunk, making a total depth of 400 feet.

GOULD & CURRY.—Letter of the 12th says: Crosscuts Nos. 2, 3 and 4, 1900 level, have made slow progress during the week, for the reason that each showed signs of water, and we had to stop them to ascertain the extent. I am now satisfied that it amounts to nothing, and work is resumed in all of them. Joint east drift 1700 level was advanced 58 feet and is now in 300 feet from the lateral drift; good progress will be made at this point hereafter. The repairing of the main shaft progresses well, 12 new sets having been put in place. It will require 10 sets more of new timbers to complete the work. There is still a very heavy flow of water at Osbiston shaft, but we are still sinking, having made 15 feet during the week; total depth, 400 feet.

CALEDONIA.—Letter of the 11th says: Since last report the east drift, 1600 level, has been extended 40 feet. The ground in the face is

Continued on page 44.

Continued from page 34.

42 millions of piecettes (the piecettes has sensibly the sams value as the franc), agreed to in 1870 by the house of Rothschild's, and to reimburse them for thirty annuities of 3,750,000 francs, the government conceded to them the monopoly of the sale of the products of the mines of Almaden, under the following conditions:

Ths Spanish government engages itself to deliver sach year, at least 32,000 frascos (hottles of 34.507 kilograms, or 75 Spanish pounds), that is, 1,104.224 tons. The value of the mercury furnished to the Rothschilds is fixed according to the course of metal in the English market. Ths minimum admitted is six pounds sterling (151.20 fraucs, or ahout that); if ths price of the metal should descend helow this figure, ths government would not receive less than six pounds sterling per frasco.

From six to eight pounds the profits are shared equally hetween the two contractors. Above eight pounds, the Rothschilds receivs one-third and the treasurer two-thirds.

Thus, the price of mercury heing, for example £14, the Spanish government would recsive per bottle:

1st. £6 as a minimum. 2d. £1 from ths first profit of £2. 3d. £4 from the second profit of £6, in all £11.

Thus the mercury enclosed in bottles is placed at Almaden itself in the hands of a representative of the houss of Rothschilds and the Administration, and the establishment finds itself dischargsd from all care and all expenss of selling, consequently of all operations which are little in harmony with tbe true functions of a government of any kind. The treasury profits likewise, at reasonable rate, hy any elevation of the price, an elevation which it is without douht not in condition either to produce or to maintain.

Nothing is more variable in fact than the price of mercury in the London market, supplied almost entirely hy the miues of Almaden. Idria does not produce more than 370 tons, while 1,200 comes from Spain; and America whose productiou is nearly equal to that of Almaden, consumes itself its products. This is not to say, that the production of the New World does not powerfully influence the value of mercury; one may, nevertheless, regard as certain that a notable part of the variations in the price is due to operations purely commercial. It was in fact, in 1873, 1874, 1875, very far from the old pricc of £6.

The avcrage prices in the London market have heen the following:

YEARS.	PRICES.			
	£.	sh.	d.	per frasco.
1865	7	19	4	"
1866	7	5	8	"
1867	6	17	1½	"
1868	6	17	"	"
1869	6	17	"	"
1870	7	18	8	"
1871	10	9	0¾	"
1872	11	11	2¾	"
1873	15	2	7	"
1874	21	6	10½	"
1875	14	4	0¾	"
1876	9	3	10	"
Average	10	0	5	"

The lowest pricc from 1865 to 1876, was £6 (Dec., 1865); the highest, £26, in Nov., 1874.

Let us now place in comparison to the price of selling, the complete cost of producing the ton and the frasco of mercury during the last five years. This cost results from the following tahle:

I. General State of Expenses in the five years, 1870-75.

NATURE OF EXPENSES.	1870-71	1871-72	1872-73	1873-74	1874-75
	Francs.	Francs.	Francs.	Francs.	Francs.

Distillation and boteling	13.60	14.10	25.60	32.10	23.00
Shops	24.10	20.90	15.20	17.90	7.00
Sundries	20.90	22.00	16.70	22.10	17.00
Hospital and chapel	17.00	14.30	14.60	17.40	12.70
Domain of Castilseras	1.50	0.20	1.50	0.80	
Extra Expenses					
Total	1,307.10	1,360.80	1,222.20	1,515.40	1,323.40
Cost per frasco	45.10	47.27	42.17	52.29	45.67

Let us see also what have heen ths quantities of ore treated and of mercury produced in the same time:

Years.	Ore Treated.	Mercury Produced.		Average yield.
	Tons.	In tons.	In frascos.	Per Cent.
1870-71	15,867.039	1,185.007	34,341	7.47
1871-72	15,835.340	1,135.046	32,803	7.17
1872-73	10,094.436	1,155.280	33,479	7.18
1873-74	16,370.750	970.104	28,237	5.00
1874-75	18,815.680	1,264.355	36.640	0.72

We give in the following tahle the relative amounts of the production of the principal countries which produce mercury; one can easily get from it an exact idea of the relative importance of Almaden to the general production.*

Years.	Spain.	Austria.	Hungary.	Italy.	United States.
	Tons.	Tons.	Tons.	Tons.	Tons.
1864	1,057.6	291.1	32.4	"	1,633.6
1865	1,078.3	192.3	42.7	"	1,928.8
1866	055.0	183.5	55.7	"	1,600.3
1867	1,095.1	271.8	00.9	"	1,276.0
1868	1,014.0	236.8	42.7	"	1.170.7
1869	1,123.7	316.0	33.7	"	1,163.3
1870	1,345.3	309.0	25.0	"	1,013.5
1871	1,157.0	375 7	18.0	"	1,100.0
1872	1,232.0	333.4	15.3	55.	1,045.8
1873	"	377.1	14.0	"	986.8
1874	"	372.1	13.2	"	1,182.0
1875	"	360.7	18.0	"	1,853.1

We will finish this study of the deposits of mercury at Almaden hy a rapid exposition of their history. This retrospective view cannot but aid in a hetter comprehension of the actual situation of the mines.

*From M. Von Lindheim, *Kohle und Eisen im Welthandel*, Vienna, 1877.

To be Continued.)

OSTRICH PEPSINE.—M. Alfred Ehelot, in an article in the *Revue des Deux Mondes*, on the means employed in the Argentine Republic to protect settlers in the Pampas from the Indians, gives some curious statements with regard to ostrich pepsine. The soldiers never could resist an ostrich hunt when they saw a male ostrich, as is the custom of that hird, taking out its young hrood for food and exercise. The parent hird generally escaped, leaving its young in the hands of its enemies. Whcn other food was scarce they ate the young ostriches. Some portious of the flesh of these hirds, when young and fat, are reckoned dainty hy the Indians. Whilst eating the ostrich the Indians always carefully put aside the stomach in order to collect the pepsine whicb it contains. "The stomach of the ostrich," says M. Ehelot, "is celehrated for its incredihle powers of digestion. The abundance of pepsine, to which it owes this faculty, has created among the Indians a curious commercial fraud. They dry it and sell it literally for its weight in gold. It is used for the purpose of restoring worn-out stomachs."

The idea is too "good to he lost sight of," and we shall no douht even hear "ostrich pepsine" addcd to the innumeral number of "patent medicines," with which the world is afflicted.

A NOVEL WALL COVERING.—*Engineering* states that of late, great improvements have heen made in the preparation of wood for wall covering. The wood is cut to the thicknoss of paper, and by a peculiar process stuck on the paper, which serves as a protection against the influence of the walls on the graining and color of the wood. The delicacy of the machinery employed in cutting so thin a veneer may he gathered from the fact that the leaves are cut out of an inch of white maple wood, and 125 out of wood with every open grain, such as oak and walnut.

AN ALLOTROPE OF LEAD.—It was hut recently annouuced that a Gcrman scientist, Schnetzenherger, had discovered an allotropic coudition of copper. It is now announced that the same scientist has discovered au allotrope of lead. Both disooveries were made by eleetrolysis.

PROF. DANIEL C. GILMAN, formerly President of the University of California, has heen elected President of the American Social Science Association.

Foothills of the Sierra.

[Read before the California Academy of Sciences by B. B. REDDING.]

Geologic Formation.

The western hase of the Sierra Nevada hordering ths Sacramsnto valley, is known in this State as the foothill region. These foothills extend from Reading at the northsrn end of the valley to Caliente at the southern extremity, a a distancs of 350 miles. I am indehted to Mr. A. Bowman, formerly of the State Geological Survey, for the following description of the formatious of this portion of the State. He says: "Gsnerally speaking, there are gradually rising low outliers of upper tertiary gravels, sands and clays all along the western hass of the Sierra. They ars often capped with volcanic matter and cut through hy erosions. The dry winding arroyos through the flattish foothills are familiar to every oue who has followed along ths sdge of the Sacramento and San Joaquin plains. These erosions in soms placss cut down into the middle tertiary and evsn into the cretacsous heds; hut there is little surface area of the latter. Down on the plains all is covered up hy the Recent.

"Patches occur of middle tertiary and upper tertiary where denudation has removed great masses of tertiary country with, these exceptions; for example, at Millerton on hoth sides of the San Joaquin. A patch of middle tertiary hills about three by ten miles is there seen; and at Ione valley, several miles square of steep hills of this period are laid down in slightly pitching heds. The tertiary formations reach away up into the Sierra in the shape of ancient river deposits. They change at from 300 to 1,500 feet altitude into fluviatite deposits; although a large portion of the plains tertiary, to helow the present sea level, is also fluviatite, interhedded with lacustrine or marine, sometimes (apparently) in alternate order.

"The surface areas may be said to change, going eastward, from recent to upper tertiary (pliocene), as the soil helongs ahove or helow the volcanic outflows; and thcu to the slate and granite formations of the Sierra, extending to the Summit.

"The cretaceous formation shows scarcely any surfacc area along the base of the Sierra except in Shasta county; althougb from Folsom north, the ravines and canyons expose its edges; especially north of Oroville, at Reading's ranch, and from there north to Pit river, the flat country is all cretaceous, the tertiary heing mostly removed by denudation. The same is true of patches hetween there and Oroville. The patch hetwecn Fort Reading and Pit river is about 20 miles square. The foothill cretaceous of Butte aud Shasta counties is overlaid by the Shasta coal measures, which are, I think, middle or upper tertiary; and these again hy the upper tertiary formation of the ancient river gravel period and hy the volcanio outflows from the Lassen volcanic chain. No cretaceous rocks have been identified intermediate hetween Folsom and Tejon pass. Lithologically, the cretaceous beds are much more silicified and compacted than the tertiary. They are the shales and conglomerates fouud in these regions; while the tertiary are often loose and fragile, and scarcely worthy of classification in the harder category. Both are very regularly hedded and only moderately tilted here; while on the opposite side of the valleys of the Sacramento and San Joaquin, they are both tilted and altered—remarkahly so in comparison with those on the east side, and in proportion to their age, generally speaking.

"The older rock formations of the Sierra foothills are, in the main, granites south of Fresno river, aud slates north. The slate region contains patches of granite, often several miles square; and there is hetween Folsom and the Central Pacific railroad a large patch, eight or ten miles square at the least, extending from the valley to near Auhurn.

"The granite region at the south has also patches of slate. Opposite Visalia, at the edge of the valley, are two isolated patches 10 by 12 and 10 hy 15 miles.

"It remains only to trace the houndary between the slate north of Fresno river and the tertiary of the valley. Along this line, heginning at the south, are the Buchanan copper mines, Indian Gulch and Snellings near the western Mariposa county line; Lagrange, and Knight's Ferry near the western Tuolumne line; Telegraph City, Campo Seco, Michigan Bar and Mormon Island near the edge of Calaveras, Amador and El Dorado—in short, a line separating these mountain counties from the valley counties, or very nearly. Farther north the framers of the counties did uot study the soil. In Placer county, Rocklin on the west and Auhurn on thc east mark the granite limits; and from there north in Yuha to Oroville in Butte county the first steep foothills of the Sierra are of the slate formation.

"The flat-bedded, unalterecd formations of the foothills described as upper tertiary, rise to very different altitudes in different places. The Oroville Cherokee mesa is, if I rememher aright, considerahly over 1,000 feet above the sea at the Cherokee end. Similar isolated middle and upper tertiary (miocene and pliocene) hills are found left as remnants, all along ths bass of the Sierra south of Oroville, while to the north thsy are plastered up against the Sierra with a cretaceous hase and pressrved hy a volcanic capping covering nearly the whole country.

"The slates and granites extend to the summit of the Sierra, ths line hetwesn the granites of the south and the slates of the north running slantingly from the point mentioned on Fresno river through the heart of Mariposa county towards Lake Taboe in a tolerably direct line."

Climate.

From Reading in the northern end to Sumner at its southern extremity, as has hesn stated, is a distance of 350 miles. The mean annual average tempsraturs of Reading is 64.14°. The lowest point to which the thermometer has fallen since a record has heen kept, was 27°, in Decemher, 1876. Its annual average rainfall is 48.05 inches. Sumner, at thc southern end of the valley, has an annual average tsmperaturs of 68.29° and an average rainfall of four inchcs. The lowest point to which the thermometer has fallen at this place was also 27° on the same day in Dscember, 1876. There is a remarkable uniformity in the climate throughout the Sacramento valley. In it a differsnce of five degrees of latitude, hetween 35° 30′ and 40° 30′, only lowers the annual averags temperature 4.15°. The diffsrsnce of the annual average temperature hetween corresponding dsgrees of latitude in the Atlantic States, at an equal distance from the ocean, is more than eight degrees.

It has been found that the foothills of the Sierra, up to a hight of about 2,500 feet, have approximately the sams tempsrature as places in the valley having the same latitude. It has also heen found that, with increased elevation, there is an increase of rainfall over those places in the valley having the same latitude; as, for illustratiou, Sacramento, with an elevation ahove the sea of 30 feet, has an annual mean temperature of 60.48°, and an average fall of rain of 18.75 iuches; while Colfax, with an elevation of 2,421 feet, has an annual mean temperature of 60.05°, and an average annual rainfall of 42.72 inches. This uniformity of temperature and increase of rainfall appears to he the law throughout the whole extent of the foothills of the Sierra, with this variation, as relates to temperature, namely, as latitude is decrcased the temperature of the valley is continued to a proportionally greater elevation. To illustrate, approximately, if the temperature of Reading, at the northern end of the valley, is continued up the foothills to a hight of 2,000 feet, then the temperature of Sacramento, in the center of the valley, would he continued up to 2,500 feet, and that of Sumner, in the extreme southern end of the valley, up to 3,000 feet.

The increase of rainfall on the foothills in the latitude of Sacramento due to elevation is ahout one inch to each 100 feet. South from Sacramento the proportion dccreases, until, at Sumner, the increase due to elevation is hut half an inch to each 100 feet. This is shown hy the record kept at Ft. Tejon, in the Tehachipi mountains near Sumner, at an elevation of 3,240 feet, where the annual rainfall is 19.53 inches. There is no record kept at any point in the hills above Reading, hut probahly, in this latitude, the increase due to elevation is ahout one and a half inches to eacb 100 feet.

The increase of precipitation on the hills at the northern end of the valley gives greater deusity to the forests, and permits them to grow at lower elevations than in the southern end of the valley. At the same time the difference in temperature is so small that the character of the vegetation of the hills at each end of the valley is not dissimilar. The trees that are found in the vicinity of Reading, at the northern end of the valley helow an elevation of 500 feet, are not found at the southern end until we pass Caliente, at an elevation of 1,300 feet.

It would seem that the temperature of the valley prevails up the Sierra to an elevation that equals the average hight of the Coast Range mountains. If a liue were drawn parallel to the surface of the ocean, from the top of the Coast Range east until it met the flanks of the Sierra, it would mark a level on the Sierra, helow which the temperature would not materially differ from that in the Sacramento valley. This fact is probahly to he ascribed to the prevailing southwest return trade-wind, which hlows over the State from the ocean for more than 300 days in the year; passing the summits of the Coast Range, but small portions descend into the valley, the remxindcr reaches the sides of the Sierra at ahout the level of the summits they have passed.

Arborial Vegetation.

At the northern end of the valley, at an elevation of 500 feet above the sea, of the California oaks arc found *Quercus lobator*, *Sonomensis chrysolopis* and *Wiselzenii;* of pines, only the nut or digger pine, *Pinus sabiniana*; the buckeye, *Æsculus Californica*; and chcmisel *Adenostoma fasiculata*. This is the characteristic arhorial vegetation throughout all these 350 miles. Its presence everywhere shows increased rainfall over the valley, and similarity of temperature to that of the valley. Our pasture oak *(Quercus lobator)* is found at lower elevations in the valley, hut always on moist land or near river courses, proving that it demands, in addition to temperature, the increased moisturc. In the southern end of the valley this vegetation prevails at higher elevations, because it there finds the proper temperature and moisture. Wherever on the foothills any of the trees named constitute the predominant arborial vegctation, it is evidence that the tem-

peratnrs is the same as that of the valley, and that plants that can be successfully grown in the valley can be grown to as high an elevation on the hills as these trees abound. If one tree were to be taken as the evidence of this uniformity of temperature, it would be sabins (the nut or digger) pine. It is never seen in the valley or on the hills below an elevation of about 400 feet. It is not found at a higher elevation than that in which the temperature is the same as that of the valley. It is never found in groves, but singly among other trees; yet it prevails throughout these 350 miles of foothills.

While the vegetation is more dense on the hills at the northern end of the valley, due to increased precipitation, there are also local differences, where there is similarity of soil, due to exposure. Throughout all the lower hills the greatest number of trees is found on gently sloping eastern, northeastern and northern hills, which necessarily are more moist and cool. The southern aspects contain less trees, because exposed to the direct rays of the sun and to the full force of the prevailing winds.

Area of Foothill Region.

On the line of the Central Pacific railroad, the foothills commence at Roseville, which has an elevation of 163 feet. From this point to Colfax—elevation 2,421 feet—in a direct line, is a distance of 32 miles. To allow for all possible errors, it would be safe to estimate that the width of the foothills, where the valley temperature, prevails, is 20 miles. This region, therefore embraces a tract of country from Reading to Sumner 350 miles long and 20 miles wide, or 4,480,000 acres. The principal towns in this part of the State are Oroville, Nevada, Grass Valley, Colfax, Auburn, Newcastle, Georgetown, Placerville, Coloma, Jackson, Sonora, Columbia, Mariposa and Havalah. In the vicinity of these towns and also near the line of the Central Pacific railroad the land is occupied by settlers. It would be using a large figure to state that half a million acres of these foothills have been pre-empted. If we estimate that another million is composed of lands granted to the Central Pacific Railroad Company, ravines, river-beds and lands too rocky or precipitous for cultivation, there would remain nearly 3,000,000 acres of land, all of it timbered, all having abundant rainfall, in a semi-tropical climate and to which title in 160 acre tracts can be acquired by settlement and complying with the rules of the United States Land department. Throughout the whole region everliving springs are numerous, and in those parts where there has been placer mining, there are many canals from which water by purchase can be obtained for irrigation. The immense precipitation that takes place during the rainy season along the western face of the Sierra, passes through this region in streams that are tributaries to the Sacramento and San Joaquin. Within this distance there are 54 of these principal streams, whose waters are perpetually adding to the volume of the Sacramento and San Joaquin.

Adaptation to Cultivation.

Every agricultural product that can be grown in the valley, including the semi-tropical fruits, can be grown with equal facility in these foothills. Ordinarily the land has to be cleared of the trees found upon it, and cultivation must be continuous, for on the whole western face of the Sierra, the native trees when cut, or burned down, are rapidly replaced by a new growth of the same kinds.

These lands are found to have all of the requisites for the successful growth of orchards. Fruit trees thrive better upon them than on the lands of the valley. None of the many theories advanced as to the cause of the treeless condition of many plains and prairies, having ample rainfall, seems to be entirely satisfactory, but experience has demonstrated that orchards grow best and thrive with less artificial aid on lands that in a natural condition are covered with trees.

The increasing exports of small fruits, such as strawberries, blackberries and raspberries, from the vicinity of Newcastle and Auburn, and their superior size and quality, prove that this region is better adapted to their culture than any place yet found on the level lands of the valley. The peaches of Coloma have a stall reputation for flavor and size. The apples of Nevada and Georgetown are equal in size, taste and keeping qualities to the best imported from Oregon. The Oroville oranges have been pronounced equal to the best Los Angeles. The vine grows with luxuriance and bears abundantly wherever it has been planted throughout all this region. The wines of Coloma have more than a local reputation. Persons competent to judge assert that wine from grapes grown on the foothills is free from the earthy taste that characterizes much of the wine of the flat land of the valleys. They also express the belief that if ever wine is to be made in California as light as that from the Rhine, and as free from alcohol, the grapes will be grown in the higher elevations of the foothills, where snow falls and remains on the ground a few weeks each season. It is said that the long summers and great heat of the valleys develop the saccharine matter in the grape, which, by fermentation, is converted into alcohol.

The Lands Open to Settlement.

There is but one Spanish grant in all this region—the Fremont grant in Mariposa. The land, therefore, can only be obtained from the Government, in tracts of 80 and 160 acres. A monopoly of the land in large estates is consequently impossible. The character of the country, being of rolling and rounded hills, prevents the possibility of very large farms. Experiments have shown that the soil is more productive than the dry plains of the valley, but of course it does not yield crops as largely as the deltas and bottom lands of the rivers. It is certainly better and more productive than lands similarly situated in France, Switzerland and Italy, which now sustain a population of millions. Wood is everywhere to be found, and in this region north of Oroville there is an abundance of water in streams and springs not yet appropriated. These lands have remained open for settlement, because, up to the present time, sufficient government land could be found in the valleys. The legislation by Congress has been and still is unfavorable to their appropriation for agriculture. The river bars and benches of this region originally contained the placer gold mines. Positive legislation by Congress forbid their survey for many years after the State was admitted into the Union. When surveys were ordered, the Land Department at Washington was so fearful that they would be occupied by farmers to the injury of the miners, that more than 1,000,000 acres were reserved as mineral land. The placer mines of these foothills have ceased to yield gold, even at Chinese wages, for the past 10 years, yet the Land Department at Washington continues the mineral reservation on these lands. The effect of this is to increase the expense of obtaining title from the Government, and thereby settlement of this region has been retarded. Where a farmer settles on land that has been reserved as mineral by the Commissioner of the General Land Office, the expense has to be borne by the settler, of showing, by testimony, that his farm contains no mines, and that it is only valuable for agriculture. There are 2,000,000 acres of these lands, on which there is no mineral reservation, and which can be obtained by homestead and preemption as cheaply as were the lands in the valley. It cannot be but a few years before the unwise policy of reserving lands as mineral, that, in fact, are not mineral, will be abandoned, so that these lands can be obtained by settlement, pre-emption and homestead as cheaply as other lands.

As I have shown, there are more than 3,000,000 acres of these lands open to settlement, fallow from the flood, waiting for occupants; capable of supporting a population of 100,000 people, if they will but cultivate them; situated in a semi-tropical climate, and, in all the higher regions, free from miasma. One need not be a prophet, nor a son of a prophet, to foretell that, before many years, the agriculture of California will become varied, and cultivation will not be confined to one cereal. Then the foothill region of the Sierra will be occupied by a prosperous and happy rural population.

Useful Information.

The Care of Shop Tools.

The *American Machinist* has some important suggestions concerning the advantage of care and system in the treatment of shop tools. First cost of tools seldom represents their ultimate cost, whether it becomes necessary to repair them or not. If a good mechanic makes a tool last a year in constant usage, while his careless neighbor uses up one of the same kind in six months, the cost of the latter should be accounted twice that of the former. When repairs are made their value must be added in computing the whole cost of the tool.

One primary reason why some shops can show a greater profit on a given amount of work is because they get more service out of their tools. This is just as evident when the tools are cheap as when they are dear, for the products of mechanical labor fluctuate the same as the first cost of tools; and if a large part of the income of the business goes for working tools and repairs to the same, balances on the right side of the ledger are likely to be diminutive, if indeed they appear at all. It is the first requisite that tools and machines should be adapted to the work to be performed. Fine tools should not be used on heavy, coarse work. They must also be kept in good working order, cutting edges well sharpened and bearing surfaces lubricated, shafting kept well aligned, pulleys balanced, belts kept clean and pliable and at the correct tension, rust prevented, emery wheels trued up, and dirt kept out of all wearing parts.

Machines should be mounted on stable foundations and run neither above nor below the proper speed required to do the work. Small tools demand as much care as large ones, and a careless or inexperienced workman will often spoil more than the amount of his wages in files, drills, chucks, reamers, taps, dies, calipers, wrenches and the like, unless closely looked after by the master mechanic. It is therefore very essential, in order to insure proper care of tools, that workmen know just how to use them. All small tools should be laid away systematically in a dry place, when not in use. In large shops a room should be set apart for this purpose, and a man detailed to take charge of it and keep the tools in good working order. There is no part of a large machine shop from which an outsider can form a better judgment of the general management than by an observation of the tool room. The best economy is secured by securing none but the best tools at the outset, for in the long run they will be found the cheapest.

An Insoluble Cement.—A very valuable cement has been discovered by Mr. A. C. Fox, of which details are published in *Dingler's Polytechnisches Journal*. It consists of a chromium preparation and isinglass, and forms a solid cement, which is not only insoluble in hot and cold water, but even in steam, while neither acids nor alkalies have any action upon it. The chromium preparation and the isinglass or gelatin do not come into contact until the moment the cement is desired, and when applied to adhesive envelopes, for which the author holds it to be especially adapted, the one material is put on the envelope covered by the flap (and therefore not touched by the tongue), while the isinglass, dissolved in acetic acid, is applied under the flap. The chromium preparation is made by dissolving crystallized chromic acid in water. You take: Crystallized chromic acid, 2.5 grammes; water, 15 grammes; ammonia, 15 grammes. To this solution about 10 drops of sulphuric acid are added, and finally 30 grammes of sulphate of ammonia and 4 grammes of fine white paper. In the case of envelopes, this is applied to that portion lying under the flap, while a solution prepared by dissolving isinglass in dilute acetic acid (one part acid to seven parts water) is applied to the flap of the envelope. The latter is moistened, and then is pressed down upon the chromic preparation, when the two units, forming, as we have said, a firm and insoluble cement.

To Turn Oak Black.—According to the *Revue Industrielle*, Paris, oak may be dyed black, and made to resemble ebony, by the following means: Immerse the wood for 48 hours in a hot saturated solution of alum, and then brush it over with a logwood decoction, as follows: Boil one part of the best logwood with 10 parts of water, filter through linen, and evaporate at a gentle heat until the volume is reduced one-half. To every quart of this add from 10 to 15 drops of a saturated solution of indigo. After applying this dye to the wood rub the latter with a saturated and filtered solution of verdigris in hot concentrated acetic acid, and repeat the operation until a black of the desired intensity is obtained. Oak stained in this manner is said to be a close as well as a splendid imitation of ebony.

Unslaked Lime for Blasting Purposes.—Unslaked lime compressed into cartridges, or used loosely and well tamped down in the hole, using water or other liquid to saturate and expand it, is now proposed for use in fiery coal mines. It is claimed that the advantages to be derived from its use are economy in the production of coal; making less slack than by using ordinary blasting powder; lives of colliers are in less danger; the breaking and shattering of coal back of the charge—which is especially characteristic of the use of gunpowder—is avoided; and the quality of the atmosphere is rather improved by its use than otherwise.

Bleaching Feathers, etc.—The *Moniteur Industrielle* states that Messrs. Viol & Duplot have recently devised a method of bleaching feathers, which, if successful, will be welcome to many who have been unable to get at the carefully-guarded secret methods used hitherto. Their method rests on the fact that feathers immersed in resinous essences (such as turpentines and other hydro-carbureted oils from distillation of resinous juices in general, or in like oils in lavender, thyme, etc., or in bituminous hydrocarbons) are decolorated under the action of light and heat. The feathers, especially ostrich plumes, are kept in the vessels a longer or shorter time, according to the degree of bleaching wished, and at about 86° F., while exposed to light as much as possible. In three or four weeks they are dried and prepared according to known methods.

Marking Tools by Etching.—Warm the steel and apply a thin coat of white wax, and let it thoroughly cool, then take a sharp engraver (a scratch awl will not answer) and run the point through the hair, in order that the point may be coated with the least possible amount of grease, and mark the device through the wax. Apply nitric acid and allow to stand for a few minutes, then wash off thoroughly with water, and heat the article; rub off the wax with a clean rag. By a little practice any one, who can form a shapely letter, will be able to mark a tool very nicely.

Green Ink.—Dissolve 180 grains bichromate of potassa in one fluid ounce of water, add while warm half an ounce spirit of wine, then decompose the mixture with concentrated sulphuric acid until it assumes a brown color; evaporate this liquor until its quantity is reduced to one-half, dilute it with two ounces distilled water; filter it and add half an ounce of alcohol, followed by a few drops of strong sulphuric acid; it is now allowed to rest, and after a time assumes a beautiful green color. Add a small quantity of gum arabic and it is ready for use.

To Make India Ink.—A German paper gives the following recipe for making a deep black india ink, which will also give neutral tints in its half shades: Rub thoroughly together eight parts of lamphlack, 64 parts of water, and four parts of finely pulverized indigo. Boil the mixture until most of the water has evaporated, then add five parts gum arabic, two parts of glue, and one part of extract of chiccory. Boil the mixture again till it has thickened to paste, then shape it in wooden molds which have been rubbed with olive or almond oil.

Good Health.

Why are we Right-Handed?

Investigations which were very recently carried through by a French physician, Dr. Fleury, of Bordeaux, have adduced facts showing that our natural impulse to use the members on the right side of the body is clearly traceable to physiological causes. Dr. Fleury, after examining an immense number of human brains, asserts that the left anterior lobe is a little larger than the right one. Again, he shows that, by examining a large number of people, there is an unequal supply of blood to the two sides of the body. The brachiocephalic trunk, which only exists on the right of the arch of the aorta, produces, by a difference in termination, an inequality in the waves of red blood which travel from right to left. Moreover, the diameters of the subclavian arteries on each side are different, that on the right being noticeably larger. The left lobe of the brain, therefore, being more richly hæmatosed than the right, becomes stronger; and as, by the intersection of the nervous fiber, it commands the right side of the body, it is obvious that that side will be more readily controlled. This furnishes one reason for the natural preferences for the right hand, and another is found in the increased supply of blood from the subclavian artery. The augmentation of blood we have already seen suggested; but the reason for it is here ascribed to the relative size of the artery, and not to any directness of path from the heart. Dr. Fleury has carried his investigations through the whole series of mamalia; and he finds that the right-handed peculiarities exist in all that have arteries arranged similar to those of man. At the same time such animals, notably the chimpanzee, the seal, and the beavers, are the most adroit and intelligent.—*The Electic.*

The Use of Tea.

The following hints concerning the use of tea may prove useful.

1. Whoever uses tea should do it in great moderation.
2. It should form a part of the meal, but never be taken before eating, or between meals, or on an empty stomach, as is too frequently done.
3. The best time to take tea is after a hearty meal.
4. Those who suffer with weak nerves should never take it at all.
5. Those who are troubled with inability to sleep nights should not use tea, or if they do, take it only in the morning.
6. Brain-workers should never goad on their brains to overwork on the stimulus of tea.
7. Children and the young should not use tea.
8. The over-worked and under-fed should not use tea.
9. Tea should never be drank very strong.
10. It is better with considerable milk and sugar.
11. Its use should at once be abandoned when harm comes from it.
12. Multitudes of diseases come from the excessive use of tea, and for this reason those who cannot use it without going to excess should not use it at all.

Food too Easily Digested.—The healthy adult requires food which will give the stomach work to do. The stomach requires work as much as the legs or arms. The nutriment of food for such should not be abstracted and ready prepared, as, for instance, it is in milk, eggs, meat; it is better that the stomach abstract it by the process of digestion from food. With the sick and the young, however, the case is very different. The stomach of a strong man is like a quartz crushing machine, capable of doing vigorous work. That of a dyspeptic is quite different, and may need great care to enable it to do its work at all. Weak stomachs, however, may be trained by slow degrees to do their work well by giving them just the right food, properly chewed, and stopping the expenditure of nerve force in other directions so that the blood may go to it. By such a course half the dyspepsia might be avoided or cured.—*Herald of Health.*

The Nails.—The growth of the nails is more rapid in children than in adults, and slowest in the aged; goes on faster in summer than in winter, so that the same nail which is renewed in 132 days in winter, requires only 116 in summer. The increase of the nails of the right hand is more rapid than those of the left; moreover, it differs for the different fingers, and in order corresponds with the length of the finger, consequently it is the fastest in the middle finger, nearly equal in the two on either side of this, slower in the little finger and slowest in the thumb. The growth of all the nails on the left hand requires 82 days more than those of the right.

Pie for Dyspeptics.—Four tablespoonfuls of oatmeal, one pint of water; let stand a few hours, or till the meal is well swelled. Then add two large apples, pared and sliced, a little salt, one cup of sugar, one tablespoonful of flour. Mix all well together and bake in a buttered pie-dish; and you have a most delicious pie, which may be eaten with safety by the sick or well.

The Week.

The excitement of the week in mining circles has been the annual meetings of the California, Consolidated Virginia, and Sierra Nevada mines, elsewhere referred to. Another item of interest to the mining community is the re-election of Senator Jones, of Nevada, to Congress. Still another, is the fact that the first water from the Comstock has been run through the Sutro tunnel. The great pumps of the Chollar-Savage-Norcross shaft were started up and sent the water through the drift on the 1593 level into the Sutro tunnel. This is the first water ever pumped into the tunnel, and hence the significance attached to it. Hitherto, since the connection between this shaft and the tunnel was made, what water accumulated in the shaft above the 1593 level has been caught up and sent into the tunnel, but never has a drop been pumped into it before. The Gold Hill *News* says: "Not only is this fact important in itself, but it is also significant when considered in connection with the situation. The fact that preparations have been for some time going on to drain the flooded mines through the lightning drift on the 2000 level of the Savage and Hale & Norcross to this shaft, is well known. The whole plan of operations becomes at once apparent, when the fact is made known that no pumps have been placed in this shaft above the 1800 level. The purpose is plain. Mr. Sutro must take not only the water encountered in the shaft, but also that from the flooded mines, as soon as the preparations for passing it through the lightning drift are completed."

Delegate Gannon thinks the Mormons would be cravens and poltroons if they yielded their religious principles to the dictates of the Supreme Court.

Mining in 1878.

Condition, Progress and Production in the Pacific States and Territories.

As usual at the commencement of each year, we present a cursory review of the mining industries of the Pacific coast for the preceding twelve months. It has been the custom to accept the aggregate amount of hullion made each year as fairly indicating the condition and progress of our mining industries for that year. Measnred hy this standard, the year just closed could hardly he considered a prosperous one; that is, as compared with some of its immediate predecessors, its yield having heen less than that of 1877 hy more than $17,000,000, and less than that of 1876 hy nearly $10,000,000. But the increased production of these two years was due, as is well understood, to the large output of ore from the Con. Virginia and the Califoruia mines on the Comstock lode, and heyond these two properties, could he said to have no special hearing on the mining interests of the coast. As this increase was due to the two mines mentioned, so also has the recent falling off in the aggregate hullion yield been due to a curtailment of their production, and not to that of the mines generally, which, taking the country throughout, have more than kept up the ratio of advance that has now been maintained through a long series of years. There has heen, of course, as there is every year, a decline in some localities and an increase in others. The countries to he credited with an increase for the year, as compared with 1877, are as follows, viz.: California, which shows an increase of $2,068,000 in gold, with a decrease of $1,323,000 in silver, heing a net increase of $745,000; Montana's increase equals $1,118,728, all in silver; Dakota's $715,804, all in gold; Idaho shows an increase of $35,627, three-fourths gold; Oregon, $21,727, nearly all gold; Washington, $18,915, all gold; New Mexico, $74,803, two-thirds silver; British Columhia, $106,270, all gold. Colorado shows a slight increase, ahout equal parts gold and silver, the hullion receipts for the year at San Francisco from the west coast of Mexico, nearly all silver, showing an increase of $162,003. The decrease has heen, in Utah $1,049,142, and in Arizona $100,639. The hullion of Arizona consists of ahout 85% silver, and the halance gold; that of Utah heing composed 90% of silver and lead, the decline in the value of the hullion here produced heing largely due to the depreciation of these metals in the markets of the world.

Annual Production and Rates of Increase.

In the foregoing estimates we have, as in former years, adopted the statements prepared annually hy John J. Valentine, General Superintendent of Wells, Fargo & Co.'s express, and which give the total product of hullion for the entire coast, receipts from British Columhia and Mexico included, dnring the years mentioned helow, as follows:

Years.	Amounts.
1870	$54,000,000
1871	58,284,000
1872	62,236,959
1873	72,258,693
1874	74,401,045
1875	30,889,057
1876	90,875,173
1877	98,421,754
1878	81,154,622

By consulting the ahove tahle it will he seen that a steady progress was made in the hullion production of the coast during the seven years preceding 1878, the advance, when sharply accelerated, having heen caused hy an unusually heavy output from some portion of the Comstock lode. The aggregate gain made during these seven years amounted to $44,500,000, heing at the rate of $6,357,000 per year. It is needless to say that much fault is every year found with these estimates of Mr. Valentine, the local press and parties interested in each particular locality heing apt to complain that his figures fail to fully represent the hullion there produced. While there may in some cases he cause for snch complaint, the tahles prepared hy that gentleman constitute, as a whole, the most reliable data we have in the premises, and must he generally accepted until such time as something more full and anthentic can he ohtained. As regards the State of Nevada there was reason to anticipate some falling off in its gross production, the management of the two honanza mines mentioned, having advised the puhlic at the heginning of the year that such result was prohable if not inevitable. In the case of Utah, too, some decline was looked for, owing to the heavy discount on silver and the prevailing low prices of lead. Of Arizona, however, a hetter account was expected. It was universally thought that she would he ahle to maintain, if not make some advances on, her former largest annual production; and it may well he that more hullion has escaped from that Territory through Eastern channels of transit than Mr. Valentine has given her credit for. While Montana has rather exceeded, Colorado has hardly come up to general expectation; Dakota having failed hy a good deal, to fulfill the promises made hy her friends a year ago. Of particular localities, none bas been able to make a hetter showing than the Eureka district in the State of Nevada, which has turned out for the year $6,981,406, as against $5,676,057 in 1877, heing an increase of $1,305,349. The Bodie district, Mono county, Cal., has also done notahly well, as have also some of the hydranlic mines in this State; more especially several of those operating on the San Juan ridge, Nevada county.

Relative Production of Gold and Silver.

The fact that the two royal metals are now heing produced on this coast in nearly equal quantity should tend to allay the fears of those, who since the discovery of so many silver-hearing mines on American territory, have entertained a fear this metal would attain to an undue preponderance as an element of the currency. From the time that gold was discovered in California, followed soon after hy like discoveries in Australia, the increase of that metal was for many years relatively much greater than that of silver, the disproportion having heen maintained on this coast till the year 1877, when the silver yield was slightly in excess of that of gold; a condition of things that has ohtained for that year only.

Last year our domestic prodnction of silver—receipts from Mexico heing omitted—was $37,248,137; gold, $37,556,030—excess of gold, $407,893. The Comstock hullion made during the year, consisted of 45% gold and 55% silver, the so-called base hullion of Nevada having contained 30% gold. The balance of it was nearly all silver, not more than two or three per cent. of the value consisting of lead. The gross hullion yield of the coast for 1878 contained the several metals approximately as follows: Gold, 48%; silver, 48%; lead, 4%; a proportion that is not likely to he violently disturhed in the near future, and which argues strongly in favor of a retention of our present bi-metallic currency. Certainly the present aspect of affairs affords little warrant for imposing further restrictions upon the coinage of silver, to say nothing of its demonetization, as contended for in certain quarters. So far as Australia and other recently discovered sources of hullion productiou are concerned, they will no douht continue to turn out more gold than silver.

Sources of Production and the Sum Total.

It is now just 31 years since the grand discovery of gold was made in California. During this period there has heen produced in the States and Territories west of the Missouri river, hullion to the value of $1,985,527,939. Of this amount ahout $1,581,433,693 has consisted of gold, and $404,094,246 of silver. Besides this, there has heen produced to date in the several Atlantic States something like $30,000,000, the most of it in Nortb Carolina, Virginia and Georgia.

If to the tahle of hullion production given on the next page, he added the entire yield of British Columhia to date, $33,000,000, San Francisco receipts from the northwest coast of Mexico, $9,000,000, and the product of the Atlantic States, $30,000,000, we have a total of $2,057,527,939 produced from the ahove sources, all hut $42,000,000 heing from mines within the limits of the United States.

Mining in California—Hydraulic Operations.

The business of mining for the precions metals in California during the year under review was, as already remarked, fairly prosperous. Owing to a rather restricted water supply the returns from the hydraulic mines, now the principal source of gold production in this State, fell a little short of what might otherwise have heen expected. There was, however, not much ground for complaint, and with an average amount of rain the coming year will see a large crop of gold gathered hy this class of miners, who employed the leisure afforded hy the last dry season to a good purpose, their claims having, as a general thing, heen put in excellent shape for future operations. Placer, Nevada, Sierra, Bntte and Yuha counties, as heretofore, continue to he the most active and productive centers of hydraulic mining, although some very snccessful enterprises of this kind are heing carried on in Amador, El Dorado aud Plumas. In Trinity and Siskiyou, where this industry was introduced at a later period, it is also meeting with a gratifying success; the conditions for prosecuting it profitably heing in some respects hetter there than in any other part of the State. Water in these more northerly counties is more easily ohtained, and for the extent of the mines, is in hetter supply than in the older hydraulic districts. In the matter of outlet, ahsence of indurated gravel and barren material, unwieldly houlders, etc., they are also hetter situated; and there is no douht hut these counties, more especially Trinity, offer just now the hest openings for investment in this department of mining, to he found on the coast. It should he remembered, however, that these opportunities, even there, are not numerous; the hydraulic deposits of Trinity heing confined to the auriferous helt, that strikes centrally across the county, snd to which all the mines there, including the hars along Trinity river, are indehted for their enrichment. Several of these hars afford the hest possihle chances for inaugurating permanent and paying hydraulic operations. Buckeye mountain, Brown's ridge and Oregon mountaiu, with one or two other similar elevations, also offer exceptionally good inducements for the investment of money in this branch of mining. Appurtenant to some of these properties are fine water privileges that belong to the Buckeye Mountain Ditch & Mining Company, heing one of the most valuahle in the State. That these natural advantages have not heen turned to a more practical account, has heen owing to the fact that the most of these properties have heen in the possession of the pioneer miners and early residents of the county; a class, not overly ambitious or covetous of money, and who, so long as they could realize moderate wages working their claims with such water as the rains afforded, and in a small way, were averse to the exertion and hother necessary to outfit and insure from them a larger production. For many years, too, Trinity heing remote and difficult of access, was not much visited hy capitalists or their agents, or others desirous of finding good openings for the profitahle investment of money. Since the extension of the railroad to its horders, affairs in this county have hegun to change. Experienced hydraulic miners from older localities have gone there, and appreciating the situation, have managed to acquire interests that under their skillful management have already become valuable; and as the attention of our moneyed men is now heing turned strongly toward Trinity and Siskiyou, it may he expected that hydraulic mining will soon undergo a marked expansion in this northeru section of the State.

Drift Mining.

The drift diggings of California have turned out well of late, considering how small a number of claims have yet been opened up and placed in good working condition. The huried channels of the ancient rivers afford here a wide and profitahle field for the prosecution of this style of mining; the only drawhack to this class of ventures heing that they require a considerahle outlay of labor and money hefore making any return. It consumes also, in most cases, a good deal of time to sink the shafts or run the tunnels necessary to reach and work these deposits. Still, with the appliances for hastening this kind of work, now within easy reach, this objection hecomes less formidahle, while a hetter knowledge of the exact levels on which the exploratory tunnels should be run, enahles the engineer to avoid the mistakes which formerly proved fatal to so many of these enterprises. The drift claims at Forest City, Damascus and Michigan Bluff, continue to yield, as they have done for many years, large amounts of gold dust. Many other claims, more recently opened elsewhere, are also heginning to make good returns; while others, having nearly completed their shafts or tunnels, will most likely he producing in a very short time.

Vein Mining.

This, hy far the most important branch of our mining industries, has, as already observed, heen attended during the past year with a full average measure of success. In California our gold-hearing quartz mines have produced fairly, and with their accustomed evenness. If in this department of the business we have hut few startling ore-finds to note, so also are there hut few disastrous failures to record. Throughout the entire southern section of the State, with the exception of Mono county, vein mining has made less progress than was at the commencement of the year hoped for. In Tuolumne county it has experienced some revival, and the outlook there may he said to have heen much improved. In the more central and northern group of counties this industry has also made fair headway, the Idaho, Sierra Buttes, Plumas Eureka and the Black Bear mines having kept up their usual large production, while a numher of otber properties have developed promising ore bodies during the year. In a district named the Silverado, situated in Los Angeles county, a considerahle numher of argentiferous lodes were discovered during the past summer, and some progress made in the work of their development. How rich or permanent the deposits will prove remains to he determined. There seems to be a good prospect, however, of some payiug mines being found there.

Mono County.

For the past year or more this county has heen a central point of attraction hy reason of the many rich gold-hearing lodes that have heen discovered and partially opened up in the Bodie district; a locality that for the preceding 12 or 14 years had heen almost wholly neglected. The mines here are worthy of attention, not only on account of their large actual production, hut also their great prospective merit, there heing at least a score that promise to develop into as good properties as the Standard or Bodie, thus far the most productive mines in the district. As the resuscitation of these mines was primarily due to the efforts made hy the present owners of the Standard to outfit that property and place it on a paying basis, it may he worth while to relate hriefly some of the circumstances connected with the history of that mine. The Standard was owned in the first instance by two German miners, who, up to the month of Septemher, 1876, had worked the ore with good results, hut in a small way, arastras only heing employed for its redaction. At that time the Cook Bros. hought it for the sum of $67,500, and worked it with such effect that they were ahle hy the next Septemher to pay a first dividend from its net earnings of $1 per share, aggregating $50,000. A like dividend has heen repeated every month since, and will prohahly he kept up for many years to come, it heing estimated that there is now sufficient ore developed ahove the 450 level to yield $3,000,000, with a prospect of its extending indefinitely downward. Not less than six valuahle ledges, varying from 15 inches to 15 feet in thickness, some of them of extraordinary richness, have heen opened up, or rather discovered, already, within the limits of the company's claims, which are 1,500 feet in length hy 1,200 in width, and not yet more than half prospected. More than one-half of the 50,000

shares of this company belong to Messrs. Seth and Daniel Cook of this city, who were associated with John F. Boyd and George Story in the purchase of the property. The balance of the shares is held in few and strong hands, this stock being rarely offered on the market. The entire width of the Staadard ground, and for some distance on each side, including the Bulwer and Belvidere mines on the west, and the Summit on the east, appears to be composed of one vast aad continuous ore channel, filled with a system of veins branching from or interlacing with each other; some of which carry very high grade ore, while others are of less value, but rarely do the assays fall below $15 or $20 per ton. The ore in all these veins is of a homogeneous character, beiug generally soft, stratified, free from sulphurets, aud carrying fine free gold well diffused throughout the vein; though containing seams very frequently of extraordinary richness—averaging several thousaud dollars per ton. The ore also contains a large proportion of clay, which seriously interfered with milling, until this compauy introduced the eilvor or pan process, which enables them to savo fully 90% of its value. The compaay has a 20-stamp mill, which will be enlarged the coming spring, after which the dividends will ao doubt be increased in a corresponding ratio.

The monthly product at present is about $100,000, the average value of the ore worked being about $70 per ton. The company has an incline shaft followiug the ledge at au anglo of about 40 degrees to the depth of 835 feet, through which the mine has thus far beeu worked. A now perpendicular three-compartment shaft is going down rapidly, haviug already reached a depth of about 800 feet, and will ultimately be carried to auy depth required for the future working of the mine. A suspended wire tramway conveys the ore at a nominal cost from the hoisting works to the mill. From present appearances, the Standard mine will continue to pay dividends for a lifetime. Happily all adverse claims have beea settled, and the titlo is perfection itself, embracing everythiug from a Uuited States patent; down to the recent school-section-State-title dodge. The total product of the Standard siace it passed under its present management amounts to over a million dollars, of which $850,000 have been disbursed to shareholders in 17 consecutivo monthly divideads, constituting as good a record as attaches to any miue on the coast.

The Bodie mine to date has also turned out considerably over a million dollars, a large proportion of which has consisted of net earnings and been paid to the shareholders in moathly dividends, none of which have yet been intermitted. Besides the Bodie, two or three other promisiag mining districts have lately beea discovered in Moao county, of which the Indian and Lake would seem to be the most important.

In the State of Nevada

There is little calliag for special comment except the shriakage of ballion production on the Comstock rauge, through the causes already alluded to. It may further be etated in this connection, that the year has failed to bring with it the ore developments elsewhere along that range hoped for at its commencement; and taken altogether, the mining outlook along the Comstock cannot be said to be just now particularly encouraging. With a valuable ore find, however, in the Sierra Nevada, Ophir, or at ether point of deep exploration, affairs there would no doubt speedily mend, aud confidence be so far restored, perhape, as to render a coutinuation of active explorations still possible. The resulte of the current year will go far toward determining this latter question. The Sutro tuunel, after a period of nearly ten years spent in its construction, reached the Comstock lode, its objective point, toward the end of the year; the event haviag ae yet been productive of no very marked results, though doubtless it will he of much service in aiding to draia the mines, as well as tend to promote their ventilatioa.

Among the New Mining Localities Discovered in this State During the past Year

The Pyramid and the Paradise districts are the most prominent. Both have attracted much notoriety, and for hoth a good deal of merit has beea claimed. To what extent they deeerve either, remains, however, to be seen. The former of these districts lies in the northern part of Washoe and the other ia Humboldt county; the first has but poor and the latter only moderately good facilities for ore reduction. About eome of the newly-opened minee in this State a good deal has also been said. In this category is the Alexander, located at the westerly hase of the Shoshone mountains, in Nye county. This may be a good property, though the neighborhood has, in times past, been less noted for its euccesses than its failures. In the Columbus district, the Mount Potosi group of mines has been opened under promising conditions, the ore developments beiag already large aad the management an exceptionally good one, heing the same that engineered the Northern Belle, lying near by, to its great success.

Work has been Resumed

During the year on several of the old mines iu the State, upon some of which it had for a long time been suspended or been prosecuted without system or energy. In this list we have the Highbridge, at Belmont, which an Eastern company, after an expenditure of nearly a million dollars, disposed of to a party of practical minere for less than a tithe of that sum. Since resuming operatioas there the presont owners have recovered the faulted lode aad are in a fair way to realize a fortuae from their purchase At the town of Aurora, in the Esmeralda district, a shaft is being sunk to explore a series of the more promising lodes iu that locality, which, after some superficial prospecting, was abandoned many years ago. As the parties who have engaged iu this enterprise have ample means aud desiga making a thorough job of it, it may be expected that something determinate of the merits of this once noted district will be reached before loug. With this revival of work at some points, is to be coupled its suspeasion at some others. Iu the uafortunate White Pine district, the English company, abont the oaly live iastitution there, have, after keepiug up the etruggle for a long time, ceased operations, but whether permaneutly or temporarily we are not advised. In the Mineral Hill and in tho Grant districts, where also English capital was interested, operatioas drag slowly or have come to a dead stop. As cause for hoth surprise and regret it is to be observed that some Nevada companies, which for a series of years had conducted their affairs to the satisfaction of the shareholders, bave lately fallen into disfavor, the Manhattan heing an example of those that have most recently passed uader the cloud. There has also been much murmuring at the manner in which some of the mines in the Tuscarora and the Ely districts have been mauaged of late, and it is to be hoped that with the incoming year such reforms will be instituted both in this State aud elsewhere, as will leave less cause for these complaiats in the future.

Of Arizona

It may be said, that while she has not quite made good the predictions of her more sanguine friends, she has still done much during the past year to sustain her good fame as a mining country. Besides making a very creditable production of bullion, she has added considerably to her population, increased her live stock of all kinds, as well as her farming products. A large extent of new mining territory has been explored and some important mineral discoveries made; and what is of more consequence still, the Southern Pacific railroad which had before reached her western border, has again heen started ahead, aad is rapidly advancing centrally across the Territory. With this road once extended to her more important mining districts, as it soon will be, all her vital interests will he greatly quickened and Arizona begin to realize something of that prosperity, which though often predicted for her, has been long postponed.

Of our Other Pacific States and Territories

It will suffice to say the mining outlook is everywhere full of eacouragement. Utah, dispite the drawbacks already mentioned, is believed to be entering upon a year of renewed prosperity. Colorado, also, seems on the eve of a new aad better era in her mining iadustries; great gains having been made in the methods of treatiug her refractory ores, and some very important mineral diecoveriee having recently been made within her borders. Montana, having lately taken a forward etep, will not be likely to come at once to a dead halt in her progress. The extension of the Northern Utah narrow-guage railroad ie beginning to tell with good effect on the mining interests of both Montana and Idaho. Gold mining in Oregon ie in a very healthful condition, the productioa this year promising to be much larger than ever before. According to the accounts from New Mexico, that Territory is almost sure to do better this year than she did last; while Dakota, if the newspapers there speak truely, is going to speedily exalt herself ae a gold-producing country.

Table Showing the Annual and Total Yield of Bullion in the States and Territories West of the Missouri River.

WAVE POWER.—Mr. Filmer, the foreman at Painter's Type Foundry, has constructed a costly model of a machine invented by him to utilize wave power, which can be seen at Mr. Howland's office, No. 401 California St. He employs a float about 24x4 feet, which rises and falls with each wave, working a lever, and in that manner pumping water to any desirable altitude.

Coal and Mineral Lands as Agricultural Lands.

While the Interior Department and the War Department are disputiag about Indiaa bureaus and surveys, a special agent has been sent to Colorado, from the General Land Office, who has just reported (says the Washington *Land Owner*), that a large number of fraudulent entries have been made of coal laads, as agricultural lands. The Secretary of the Interior, on the 5th inst., submitted his reports on the subject to the Attorney General; and the questioa now is, whether the patents shall be cancelled through the courts?

The law aad the precedents in such cases, are simply intended to prevent great tracts of coal or mineral laads from getting locked up in the haads of speculators, who will do nothing with them. But millions of acres of coal underlying whole counties of agricultural lands, have been settled upon, all over the United States, and have never heeu known as anything else than farming lands. If the Attorney General uuderstands the matter therefore, in cases of this kind, where there has been no intentioual fraud or subverstion of the law, he will refer the whole question back to the Interior Department with a note.

It might run to this effect: That the only way for the Department to avoid being "defrauded of large sums of money" by pre-emptions of coal or miaeral lands, will he to institute a segregation of the lande by geological survey. It would not be difficult for the Department to obtain, from the maps of such a survey, areas in which the surface is most valuable, eeparated from others where the coal or material under the eurface, is the most valuable. How else cau the matter be determined equitably?

The Land Office plats ought to show what the Government is selling. It is not fraud to huy agricultural laads as such, from the Government, merely because the eeller afterwards discovers some accessory value attaching to it, or because he suspects that the buyer knew it before him. The Land Office is holding out a premium for perjury, without preventing coal land monopoly in the slightest degree.

In the organization of the geographical and geological eurveys hereafter, the waats of the Land Office, if not placed foremost, should certainly not he overlooked. It is nearest to the material wants of the people; and its surveys and maps are most directly concerned with the development of the soil and of the mine. The Pacific States and Territories are more interested even in the coal land question than is commonly supposed.

BATHING HOUSE AND SWIMMING SCHOOL.—There is a laudable movement on foot to establish a first-class bathing house and ewimming school at North Beach, S. F. The plans include a handsome building with swimming circle, dressing rooms, private baths, etc., below; and furnished apartments above. A prospectus has been issued hy E. M. Morgan and J. L. Sanford as managing agents, in which those seeking enterprises for the investment of money, are iuvited to suhecribe to the stock of this institution. The agents are at No. 80 Nevada block, where full drawinge and proposed details of plaas, prospecte, etc., can be had by those interested.

AUTOMATIC GRIP FOR WIRE TRAMWAYS.—Mr. John Samsoa, C. E., of this city, has iaveated a grip for wire rope tramways for mineral traffic. The novelty consiete in that the cars are rapidly attached to the rope and may be detached at any point on the road required, by simply putting a stop to touch a trigger on the connecting bar. Thus the necessity of conductors on the cars ie avoided, and cars loaded with mineral or grain can he dispatched in frequent succession without trouble or attendance.

AN American bank is about to be established at the city of Mexico.

A Paper of General Interest.

We invite attention to our "Aanual Mining Review" published in this issue of the PRESS. While it is impossible to speak of particular localities or properties witb much detail, where such a great extent of conutry has to be gone over, there will be found in this nrticle much to interest the mining public, as well as matter calculated to commaad the attentioa of the respective advocates of a mono-metallic, a bimetallic and a uoa-metallic currency. Through the several tables presented in this report much light is tbrown upon the questioa of hullion productien, the annual and the total yield of gold and silver, as well as the comparative iacrease of these two metals; both upon this coast and throughout the entire country beiug thereiu set forth. These tables have been compiled from the most trustworthy sources, and may be accepted as containing the most authoritative figures on this subject extaat. By consulting them it will be seen that the opinion so generally entertained that the productioa of silver has of late been largely in excess of that of gold is not well founded. Only ia a single year has this occurred, the aggregate value of the gold produced in the United States having been nearly four times as great as that of silver; and it is probable that nearly the same ratio of iacrease has during the past 25 or 30 years held good the world over. When the Comstock lode was first discovered the most exaggerated reports as to its great wealth, spread rapidly over the world, the impression everywhere obtaining that it was purely a silver-bearing lode. This having beea followed soon after by equally exaggerated reports of like discoveries elsewhere oa this coast, the above erroneous impression was intensified to a degree that filled the nations with apprehensions of an immediate silver glut; hence the crusade against this metal and its partial demonetization hy some of the leading nations of Europe. It subsequeatly transpired that the Comstock ores carried nearly as much gold as silver, and that the rumored discoveries of this latter metal in other parts of the country had but little to justify them. But it took years to bring these facts home to the knowledge of people abroad, aad eradicate from the popular mind these false impressions. With these mistaken notione corrected, it may be expected that more just and enlightened opinions upon the subject of the currency will prevail, and that both of the royal metals will continue to he employed for effecting exchanges and measuring values.

The "Golden Mountain" and the Oranges.

Mr. Redding's paper on the "Foothills of the Sierra," on our inside pages, gives origiaal facts of importance in regard to that iuteresting region. First, the geological formations are described, furnishing the foundatioa on which the horticulturist has to build. The curious fact that the climate of the foothills is more even day and night, and less marred by frosts injurious to semi-tropical fruits, thaa the valleys of the Sacramento and San Joaquin, is precisely and authentically stated; and the cause thereof is clearly explained.

Nothing is wanting to make the foothille one of the most beautiful, and the richest of horticultural regions in the world, but making use of the provisions for irrigation which the Sierra Nevada eo abundaatly afford, and directing them so that the individual land holder may derive a fair benefit from them. Examples of what can be done in this respect are not wanting; but the work is scarcely begun.

Corporations will not monopolize the water rights and the rainfall, wheu the day arrivee for the foothills to he prosperous. The people who uadertake to make homes there, will have an interest in the bounty that comes from heaven. As it has to be impounded, however, in reservoirs, and led long distances ia ditches, the corporatious that have done the work so far, are the first to reap the benefite.

If the laud holder can be protected from unreasonable exactions, while he is furnished with oaly a little water to irrigate, hie home ia the foothills of the Sierra will be bleet with such rare advaatagee that the combination seems certainly unequaled, in most other parts of the world.

THE Presidio Railroad Company, of which Messrs. A. R. Baldwin, A. S. Hallidie, A. W. Bowman, Albert Miller and others are directors, has issued a circular with a fine map, showiug the ronte of their proposed double track wire cable railroad along New Montgomery and Union etreets. It is expected that North Beach and Fort Point real estate will be greatly enhanced, and that the road will pay well; propositions that can hardly be doubted. That portion of Saa Francisco hae the best outlook.

A DOUBLE size iseue of the MINING AND SCIENTIFIC PRESS, containing eight extra pages, with an article and map of Sonora, Mexico, will appear on the 25th inet. Other original articlee, of scientific as well as industrial importance, that have been prepared for the PRESS, will be published at the same time.

DEWEY & CO'S
SCIENTIFIC PRESS
Patent Agency.

Our U. S. and Foreign Patent Agency presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system and intimate acquaintance with the subjects of inventions in our new community. All worthy inventions patented through our Agency will have the benefit of a description or an illustration and explanation in the MINING AND SCIENTIFIC PRESS or the PACIFIC RURAL PRESS. We transact every branch of Patent business, and obtain Patents in all civilized countries. The large majority of U. S. and Foreign Patents granted to inventors on the Pacific Coast have been obained through our Agency. The files of cases and official records in our office, our patent law and scientific library (already the largest west of the Mississippi), are constantly increasing. These facilities, with the accumulation of information of special importance to our home inventors, by the experience of its proprietors in an extensive and long continued personal practice, gives them combined advantages greater than any other agents can possibly offer to Pacific Coast inventors. Circulars of advice, free.

DEWEY & CO.,
Patent Solicitors,
No. 202 Sansome St., S. F.

UNITED STATES
Mineral Land Laws, Revised Statutes
AND INSTRUCTIONS AND FORMS UNDER THE SAME.

We have just issued a pamphlet containing the General Mineral Land Laws of the United States, with instructions of the Commissioner of the Land Office. The contents of this pamphlet comprise all of the Government laws with relation to mineral lands of interest to the mining community, as follows: Mining Statute of May 10th, 1872, with instructions by the Commissioner of the Land Office; Mining Statute of July 26th, 1866; Mining Statute of July 9th, 1870. Forms required under Mining Act of May 10th, 1872, as follows: Notice of Location; Request for Surveys; Application for Patent; Proof of Posting Notice and Diagram of the Claim; Proof that Plat and Notice remained Posted on Claim during Time of Publication; Registers' Certificate of Posting Notice for Sixty Days; Agreement of Publisher; Proof of Publication; Affidavit of $500 Improvements; Statement and Charge of Fees; Proof of Ownership and Possession in Case of Loss or absence of Mining Records; Affidavit of Citizenship; Certificate that no Suit is Pending; Power of Attorney; Protest and Adverse Claim; Non-Mineral Affidavit; Proof that no Known Veins Exist in a Placer Claim, etc. There is also given the U. S. Coal Land Law and Regulations thereunder. The work comprises thirty pages, and will be sold, postfree, for 50 cents. It should be in the hands of every one having any mining interests. DEWEY & CO.,
Publishers of the MINING AND SCIENTIFIC PRESS, S. F.

GOOD LAND
—IN A—
FAVORABLE LOCATION,
GUARANTEEING
Sure Crops Every Year.

The Reading Ranch,

In the Upper Sacramento Valley, originally embracing over 26,000 acres of

Choice Grain, Orchard and Pasture Land,

Is now offered for sale at low prices and on favorable terms of payment,

In Sub-Divisions to Suit Purchasers.

The ranch was selected at an early day by Major P. B. Reading, one of the largest pioneer and owners in California. It is situated on the west side of the Sacramento River and extends some 20 miles along its bank.

The average rainfall is about 30 inches per annum, and crops have never been known to fail from drouth.

The climate is very healthful and comparatively desirable. The near proximity of high mountain peaks gives cool nights during the "heated terms" which occur in our California summers.

Soft well water—remarkably sweet, pure and healthy—is obtainable at a depth of from 15 to 35 feet.

Wood is plentiful and easy to get.

Figs, Grapes, Peaches, Prunes, Almonds, English Walnuts, Oranges and other temperate and semi-tropical fruits can be raised with success on most of the tract. Also, Vegetables, Corn and all other cereals ordinarily grown in the State.

A considerable amount of the rich bottom land has already been cultivated.

Deep Soil With Lasting Qualities.

The soil throughout the tilled portions of the ranch proves to be of great depth and enduring in its good qualities. It is quite free from foul growths. The virgin soil among the large oak trees on the bottom land is easily broken up and cultivated.

The California and Oregon railroad traverses nearly the entire length of the tract. There are several sections, stations and switches, besides depots at the towns of Anderson and Reading—all of which are located within the limits of the ranch.

Land suitable for settlers in colonies can be obtained on good terms.

Are offered for sale in Reading, situated on the Sacramento River, at the present terminus of the railroad. It is the converging and distributing point for large, prosperous mining and agricultural districts in Northern California and Southern Oregon. Also, lots in the town o Anderson, situated more centrally on the ranch. Lots in both these towns are offered at a bargain, for the purpose of building up the towns and facilitating settlement of the ranch.

Purchasers are invited to come and see the lands before buying here or elsewhere. Apply on the ranch, to the proprietor,

EDWARD FRISBIE,
Anderson, Shasta Co., Cal.

The "California Legal Record."
The ONLY WEEKLY containing all the decisions of the Supreme Court of California.

(The ONLY COMPLETE continuation of the S. F. *Law Journal*.)

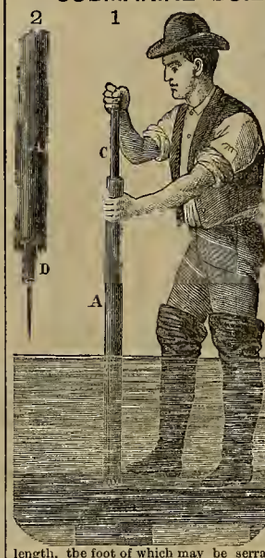
Published every Saturday, in 8 vo. size—like the California Reports—contains EVERY DECISION of the Supreme Court, as fast as rendered, with a syllabus and statement of facts, and other important legal matter. The volumes commence on the first of October and April each, and have a full index for reference and binding.

REDUCED PRICE, only $5.50 per year, or $3 per volume of six months. Remit by Postal Order or Registered Letter, specifying what date or number to commence. Back numbers furnished. Sample numbers sent free. Address,

F. A. SCOFIELD & CO., Publishers and Prop's.
No. 603 Washington street, San Francisco, Cal.

The Large Circulation of the MINING AND SCIENTIFIC PRESS extends throughout the mining districts of California, Nevada, Utah, Colorado, Arizona, Idaho, Montana, British Columbia, and to other parts of North and South America. Established in 1860, it has long been the leading Mining Journal of the continent, its varied and reliable contents giving it a character popular with both its reading and advertising patrons.

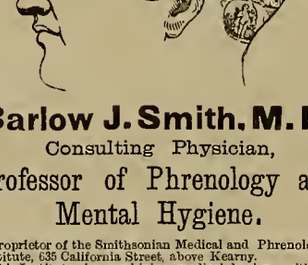
Important to Contractors
—AND—
SUBMARINE BUILDERS.



WILLIAM STACK, of Oakland, has recently patented through the MINING AND SCIENTIFIC PRESS Patent Agency, an apparatus for driving nails or spikes under water, an engraving of which is here shown. It is well-known that it is extremely difficult to drive nails or spikes under water, even if it is only submerged a few inches. These difficulties are completely obviated by Mr. Stack's device, which has been put in thorough practical operation in the construction of wharves and slips in the Oakland side of the bay.

Fig. 1 shows the application of the device, and Fig. 2 shows the construction. *A* is a metal tube of suitable length, the foot of which may be serrated as shown, so that the points will engage with the wood when the tube is pushed or driven against it. The rod or driver, *C*, has a recess or cavity, *D*, at the lower end so as to rest on top of the nail or spike shown in Fig. 2. Where the tube, *A*, is pushed against the timber in the desired position, the spike or nail is dropped in at the upper end and slides down against the timber. The rod, *C*, is then slid down on top of the nail, and by alternately drawing out and forcing the rod into the tube, the rod serves as a driver; or by hammering on the upper end of the rod the nail is driven into the wood. The tube answers both as a guide for the nail and driving rod. The tube can also answer as a guide for a screw-driving device on the end of the rod, by which lag screws may be put in place under water as well as nails. Of course the tube may be set in any position desired, so that nails may be driven at an angle if necessary. The appliance, as simple as it is, will be found very useful in many cases for bridge building or similar purposes. Address,

WM. STACK,
N. E. Cor. Fifth and Harrison Sts., OAKLAND, Alameda County, California.



Barlow J. Smith. M. D.
Consulting Physician,
Professor of Phrenology and Mental Hygiene.

Proprietor of the Smithsonian Medical and Phrenological Institute, 635 California Street, above Kearny.

This Institute, by combining medical hygiene with the various Water Cure treatments and the most powerful Electrized Horseshoe Magnet in the world, claims to cure speedily and permanently all forms of acute or chronic nervous derangements, Brain, Spinal and Heart diseases, St. Vitus Dance, Palsy, Epilepsy and all Rheumatic, Liver and Kidney troubles. The institution has for the past 20 years made a specialty of treating all forms of weaknesses and diseases peculiar to males and females. By the use of hygienic remedies and electro-motopathy the worst forms of impotency and seminal weakness in males and sterility in females are speedily and permanently overcome. Hygienic board, with or without rooms. Terms moderate. Electro-thermal, Russo-Turkish and Medicated Baths given daily. Mrs. Dr. Smith as Matron has charge of the female bathing department.

DR. SMITH has practiced Phrenology the past 30 years, and during the last 20 years has been constantly using the science connected with Physiognomy, in examining or diagnosing disease in this city, and claims to have made discoveries in the SCIENCE of Phrenology that enables him, by an examination of the head, even blindfolded, to determine the disease to which the person is constitutionally subject, or whether the disease at the time afflicting the person, is the result of accident or hereditary weakness; whether CONSUMPTIVE, DYSPEPTIC, RHEUMATIC, APOPLECTIC, NEURALGIC, LEUCORRHŒAL or SEMINAL. Especially does the form of the head indicate the strength of the uterine, genital or reproductive system. The head is also an index of the natural strength of the lungs, heart, stomach, liver, kidneys, spleen, back or vertebra, and it determines the power of the system in warding off and overcoming disease of all kinds.

Ladies or gentlemen, desirous of obtaining a thorough and correct Phrenological examinations with Fowler and Wells' charts, will meet with a respectful reception at his consulting rooms. Parties can depend upon a reliable delineation of the character of their intimate male or female friends, by presenting a clearly defined photograph.

Phrenological or Physiognomical examinations without charts, $1.50; with charts, from $2 to $3.

INVITATION TO INVALIDS

And all persons who are in any way out of health, who desire to know the nature and causes of their disease, may avail themselves of an examination through phrenology in regard to health free of charge, between the hours of 9 A. M. and 8 P. M. Sundays from 9 A. M. to 12 M

PROMPT AND SUCCESSFUL.—*Messrs. Dewey & Co:*—Gentlemen: Your Circular letter, 12th inst., informing me of successful termination of my application for patent received. Please accept thanks for the prompt and successful manner in which you have managed this business
Yours respectfully, J. H. CAVANAUGH.

DEFLECTORS,

Or Perkins vs. Hoskin.

H. C. PERKINS has for nearly two years been threatening orally and through the Press to prosecute all persons using my Patent Deflecting Nozzle, but for *good reasons*, has failed to come to time. I want miners to understand that Deflectors are still manufactured and sold, and that I will defend all suits and assume all responsibility. Mr. P. will confer a favor if he will carry out his threat, as it will afford me the opportunity I desire to again try the case, and he can rest assured that *professional dodges* will not again be allowed to *temporarily* thwart the ends of justice.

I feel confident that the Supreme Court of the United States will ultimately decide in my favor. The superiority of my invention is shown by the means which Mr. P has resorted to in trying to stop my sales. Mr. P. has so degraded himself as to circulate statements which he knows to be *false and malicious.* Notwithstanding the great number of my Deflectors in use, I have heard of but one accident, and this was caused by the breaking of the iron lever from a defect in the material and great carelessness in use. This circumstance Mr. P. has magnified into several deaths and numerous accidents. I refer to the following owners and Managers for testimonials as to safety and efficiency. Some of them have used and discarded Mr. Perkins' device in favor of my much superior one. Messrs. Gould, Gold Run, ushg 4; Spaulding, Dutch Flat, on different mines, 12; Stone, Gold Run, 2; Morgan, Little York, 6. Bisbee, Iowa Hill, 2; Briere & Wheeler, Bath, 2; McGillivry, Forest Hill, 4; Atkins, Weaverville, 2. 'I could mention scores of others, but these are sufficient.

Mr. Perkins' device is an infringement on a patent owned by Mr. Craig, who is about to institute legal proceedings to protect his rights. Miners are advised to stand from under. A word to the wise is sufficient. R. HOSKIN,

Manufacturer of Machines for Hydraulic Mining. Address, No. 29 Garden Street, San Francisco, or Empire Foundry, Marysville, Cal.

South Pacific Coast Railroad.

New Route (Narrow-Gauge.)

Commencing Monday, September 30th, 1878, boats and trains will leave San Francisco daily from the New Ferry Landing, foot of Market street, at 5:30 A. M., 9:00 A. M., and 4:00 P. M. for ALAMEDA, SAN JOSE, LOS GATOS, ALMA, and all way stations.

Stages connect with 9:00 A. M. train at Alma for Santa Cruz.

EXCURSION TICKETS will be sold Saturday afternoons and Sunday mornings from San Francisco and Alameda to San Jose, Los Gatos, and Congress Springs, and return, at reduced rates, good only until Monday evening following date of purchase.

FERRIES AND LOCAL TRAINS, DAILY.

From San Francisco.—5:30, †6:40, 9:00, 10:30 A. M.; 1:30, 4:00, 5:15, 6:30 P. M.
From High Street, Alameda.—†5:40, 7:40, 9:04 A. M.; 12 M.; 2:40, 4:00, 5:16, 6:24 P. M.
†Daily, Sunday excepted.

The Company are prepared to carry vehicles of all kinds on the Ferry, to and from San Francisco, Alameda and Oakland.

Engraving. Superior Wood and Metal Engraving, Electrotyping and Stereotyping done at the office of the MINING AND SCIENTIFIC PRESS, San Francisco, at favorable rates. Send stamp for our circular and samples.

CAUTION

To Hydraulic Miners.

The public generally and Hydraulic Miners especially are hereby notified that any parties making or using the contrivance known as the HOSKIN DEFLECTOR will be prosecuted to the full extent of the law, said machine having been declared by the U. S. Circuit Court an infringement upon my patent, the

Bloomfield Deflecting Nozzle.

The public are also cautioned against using the Hoskin Deflector because of its danger to life and limb, this device having already occasioned several deaths and other serious accidents. The BLOOMFIELD DEFLECTOR is entirely safe, its two and a half years use without accident, as well as its construction, proves it to be a reliable contrivance.

Any parties wishing to purchase the right to use these Deflectors can do so by applying to the undersigned,

HENRY C. PERKINS,
North Bloomfield, Nevada Co., Cal., October 1st, 1878.

Continued from page 37.

quite soft, showing considerable clay in the seams of the rock. The north crosscut has been extended 48 feet. The formation is the same as last week. Will probably commence cutting station for the deep winze to be sunk from this drift by the last of the week.

MEXICAN.—Letter of the 11th says: On our 1600 level ths joint Union Con. winze has been sunk and timbered to a depth of 151 feet on the slope, 12 feet having been made during the past week. Material encountered coutinues hard blasting porphyry. On our 2000 level the main north drift has been advanced 41 feet; total length from our south lins, 145 feet. The material passed through has changed to hard blasting porphyry.

BELCHER.—Letter of tbe 11th says: Tbe east drift from station on 2560 level is in 33 fest. The short station sets are all in and one set of timbers in the station proper has been put in place, a chute has been cut out and one length of track laid. All this work, togetbar with the drift mentioned above, has been done during the week. The south drift on the 2360 level is now in 504 feet, having bsen driven and timbered 35 feet during the week. The sinking of the main incline has been resumed today.

BULLION.—Letter of the 13th says: Our incline shaft has been sunk 18 feet during the past week, making total depth on slops below 2050 level of 222 feet, material penetrated has been a mixture of porphyry and quartz of a softer nature than heretofore encountered, and which admits of better progress. The incliue is now 10 feet below the 2158 level, or 2000 level of the Imperial; 2000 level, north drift, has been advanced a distance of 20 feet during the past week; material has beeu soft porphyry which admits fair progress; 2400 level, branch drift, has been advanced 20 feet, making total length of same 37 feet. The ground penetrated has been hard vein porphyry, carrying occaeional streaks of quartz. The water in main drift is gradually decreasing.

HALE & NORCROSS.—Letter of the 13th says: On the morning of the 9th inst., connection was made with the Chollar-Norcross shaft. The total length of the 2000 east drift is 894 feet. We are now engaged in cutting out for a station on tbe west side of the shaft, which will he completed in a few days. The water stande today 22 feet below the 2000-foot station. The pumps at the C. N. S. shaft were started up yesterday pumping water into the Sutro tuunel. The machinery moved off splendidly, giving perfect satisfaction. All of our machinery is running well.

JULIA.—Letter of the 11th says: Owing to the increase of the flow of water discovered in the fore part of tbis week, but little progress has been made in the southwest drift 2000 level. Water shows no signs of diminishing; as soon as it is possible the work of advancing the drift will be resumed in order to develop the favorable veiu material which it shows in its face. Have repaired 856 feet on 1800 level south drift, cut drain and laid car track. Company'e main pump as well as the donkey pump are in excellent order, notwithstanding their increased working epeed.

EUREKA DISTRICT.

CHARTER COMPANY'S MINES.—Cor. Eureka *Sentinel*, Jan. 8: Their mines are located in the center of Eureka district. The main tunnel of the company—now 630 feet in length—is so situated as to develop nearly all the claims. It lies on a level 800 feet below a point where the company are now sinking a shaft in high-grade ore, on the Needle mine. Mr. Chas. Dehman, one of the present owners, located uearly all the claims of the company during the years from 1870 to 1875, and has held uninterrupted possession of them ever since. The tunnel is being pushed forward night and day, by contractors, in a southeast direction. A body of ore, giving assaye from $9 to $44 per ton, and showing a crevice of 15 feet, has just been cut through. The State Pride series, embracing in width 1,000 feet from north to south, embracing 11 locations, are now being pierced by the tunuel. Assays of ore taken from these mines have ranged from $20 to $894 per ton. The Fire-Fly, extending north and south, shows well-defined croppings five feet wide, and will be reached by the tunnel after it has passed through tbe State Pride series. The Monogram tunnel is 40 feet long, and prospecting shafts have proven the value of this claim, which is next in the series to be developed by the tunnel and crosscuts at a depth of 200 to 300 feet below the eurface. The Altai runs north and south, and shows large and well-defined surface croppings. It lies 600 feet west of and parallel with the well-known Grant mine, and adjoius the Needle. A shaft is being sunk on the Needle mine, and very fine ore is being taken out, which is of the same character as that found in the Grant, which joins it. A sample taken at the time of our visit gave an assay value of $549, and ore from this mine has assayed as high as $1,907. The Dehman mine is 500 feet north of the Needle, and shows the same character of ore. The Plummet series lie 2,000 feet south of the Grant, and comprise four parallel claims. A tunnel is now being run iuto this portion of the property, and very fair results have been shown from assays made of the ore. Adjoining the Plummet series, on the side next to the Charter tuunel, is the Peer mine, showing large, well-defined, contact cropings, lying between the limestone on the east and quartzite on the west. The Andalusia lies west of the Peer, and shows croppings over 15 feet wids, yielding very satisfactory assays. Eight hundred fest west is the Premium. Assays from workings on this property show from $40 to $500 per ton. A tunnel 50 feet long and a shaft 50 feet deep are run on a well-defined ledge of tbe Premier. The Coronet, near Prospect Mountain tunnel, has a shaft sunk 184 feet, showing at the hottom a crevice 10 feet wide, from which assays of $500 per ton have been ohtained. Already more than $25,000 in money have been expended.

PIOCHE DISTRICT.

PIOCHE.—*Record*, Jan. 4: The Hillside company shipped on the 29th of December 20,000 pounds of base bullion, the assay value of which was $537 per ton. Yesterday they also shipped 20,000 pounds, of about the same assay value. Nearly all the men employed at tbe Meadow Valley mine were knocked off Monday. We believe it is the intention of most of the men to go to work chloriding, on shares, in tbis mine. The Hillside furnace is still running successfully and turning out bulliou. Work continues at the mine with unabated vigor. The bullion product from the Pioche mines for the year 1878 amounted to $609,841.75. The Christy Mill and Mining Company shipped from Silver Reef on the 25th and 26th of December two bars of bullion valued at $3,531.30. Bullion valued at $6,785 was shipped from this place during tbe past week.

ARIZONA.

CASTLE DOME.—*Arizona Sentinel*, Jan. 4: A remarkable cavo has been found in the Railrosd mine. It is as large as an ordinary room, and adorned with stalactites and stalagmites which are completely encrusted with yellow crystals of lead molyhdate. This cave is at one side of the vein. The Arkansaw shaft ie now down about 350 feet, in excellent ore.

PICACHO.—The new 15-stamp quartz mill was started up on New Year's day. Some 250 tous of ore are on hand at the mill, and as much more is on dump at the mine. The reserves already developed are iuexhaustible. A contract bas been made with Mr. Clark, of San Bernardino, to haul 4,000 tons of ore from mine to mill at $1.80 per ton. His teams are due here ou the 15th. The quality of the ore was fully tested by the old five-stamp mill at work there last year; it was fouud to yield from $15 to $40 in free gold.

MULE PASS.—W. S. Edwards is now out there to make surveys and to have the necessary work done on the mincs recently bought by Corbin & Co. It is expected that the Eastern company referred to will soon erect machinery and go to work iu earnest.

AZTEC.—At the Aztec, under tbe superintendence of Mr. Hunter, a large number of men are at work erecting the mill and it is expected that it will before many weeks be in successful operation.

ARIVACA.—The mill owned by the St. Louis company that is being erected on the Arivaca is approaching completion. The Waterbury com pany, of Connecticut, has recently started work on several mines under the management of Mr. Kirkpatrick.

OREGON.

THE STEAMBOAT QUARTZ MINE.—Jacksonville *Sentinel*, Jan. 1: Says Richard Cook, one of the owners: A large vein of gold-bearing quartz has just been discovered, assaying from $22 to $90 per ton. Messrs. Cook & Herd have doue about $500 worth of work during the past season. An effort is now being made to organize a stock company to work the ledge.

THE LUCKY QUEEN RENTED.—*Independent*, Jan. 1: The Lucky Queen mine has heen rented for a period of one year to a Mr. Rodebaugh, an experienced miner, who, after practical tests, is satisfied he can work the ore with profit.

UTAH.

SILVER REEF.—Enreka *Sentinel*, Jan. 8, quoting Cor. Ward *Reflex*: Speaking of San Francisco district, the writer says: "The distance from Ward is about 135 miles. The miners in Frisco were mostly idle, bnt said they would soon be on again in a few days. Merchandise is about five per cent. less here than in Ward, and costs the merchants from 10% to 20% less to lay it down here than in Ward. Business appears to be good, but chloriders say the mill companies get away with all the profits."

Salt Lake *Tribune*, Jan. 8: J. E. Clayton has returned from Silver Reef, where he has heen examining the silver-sandstone grindstones. The Professor regards it as a rich and interesting country.

FRISCO.—Cor. Salt Lake *Tribune*, Jan. 8 Everybody seems to he awaiting a change of ownere of the big mine. Both smelters shut down during the holidays. Campbell, Cullen & Co. started up on the 1st. Godbe & Co. are making some very needful improvements and relining. They will start up on the 10th of the p resent month.

THE PHYLLOXERA IN PORTUGAL.—The telegraph announces that the Portuguese government, in alarm at the ravages of the phylloxera in the proviuce of Douro, has directed local commissions to make careful investigation and iustruct vineyardists in the best modes of resisting the attacks of this foe.

THE ice blockade in the Columbia and Willamette rivers, Oregon, still continues.

The Discoveries of Scienoe in 1878.

[From our Regular New York Correspondent.]

The closing days of the year 1878 naturally suggest a retrospcctive glance at the many notable events in the realm of science, which must forever mark it as one of the most important eras in which man has made wonderful advances in bis knowledge of nature.

With the dawn of the year came the double announcement of tbe discovery of the liquefaction of oxygen by the great Frsnch scientists, Pictet and Cailletet, who curiously both arrived at the same results by processes perfectly different. If any priority should be given for the solution of this problem, it must be awarded to M. Cailletet, who recorded the fact on the 2d of December; but being a candidate for a seat in the Academy of Science, he consigned the account of his discovery to a sealed packet, which was opeued at the academic session of Decsmber the 24th, the very day M. Raoul Pictet's lstter arrived, anuouncing his succsss.

On the opening day of the year 1878, M. Cailletet accomplished the liquefaction of hydrogen, nitrogen and atmospheric air; and, but a few days after this, January 11th, M. Pictet effected the solidification of hydrogen, which proved to be a metal, a fact that was forsshowed 40 years ago, by thsoretical calculations, by M. Dumas.

As a sequsnce to these important discoveries, the closs of the year brings with it the recent discovery, by Mr. J. Norman Lockyer, that all the 64 so-called elements are merely condensations of, or modifications of a single primitive form of matter, that being hydrogen. It ie yet early to predict the full effect of Mr. Lockyer'e discovery, for as yet it has not been confirmed by others. In some of Mr. Lockyer's last experiments with the spectroscope, he appears to have even effected the transmutation of the metals, and thus accomplished the wildest dreams of the alchemist; for he found that the result of the decomposition of copper gave the spectrum of tin. It yet remains to be proved that the interpretations of the spectroscope were correct, but even if no error is discovered and Mr. Lockyer's discoveries are, in reality, what he represents them, the limit to which the results can he carried should be elearly understood. It may be possible to rednce gold and other precious metals to hydrogen, but it will never be possible to make gold from hydrogen, although such a result might appear to follow, the reason being that one of the factors in the formation of metals ie not within the control of the chemist. As an example, it has been suggested that it is easy to reduce coal to ashes, but to reconstruct coal from ashes is not to be accomplished.

The year 1878 will ever be associated with the name of Thomas A. Edison, for during this year the introduction of old, and perfecting of new inventions of a scientific character, has attracted the attention of the whole civilized world. It would be a waste of time on my part to describe the phonograph (now much improved), megaphone, phonometer and the acrophone, and the tbree great acbievements of his geniue, the improved carbon telephone, the tieimeter and the electric lamp. Of the latter I shall probahly epeak in detail in my next letter.

Of the discovery of an intro-mercurial planet by Lewis Swift and Prof. Watson, but little can he said, as probably the astronomical world will wait further confirmation of their existence, before finally accepting their presence as a fact. Not from any want of confidence in the observations of Messrs. Swift and Watson, but from the recognized difficulties under which the observations were made, permitting the possibility of error.

Space will not permit a more extended survey of the ecientific work of the year 1878, the details of which will be found in the usual annual works published for that purpose. But among the names of those workere whoee work justly entitles them to honorable mention, may he mentioned with pride, our countryman Prof. Graham Bell, in perfecting hie telephone; Mr. Stearns, in "duplexing" the Atlantic cable; of Prof. Alfred M. Mayer, in illustrations of the atomic theory by floating magnets; of Sir J. D. Hooker and Paul Bert, in their discoveries in vegetable chemistry; of Prof. Leconte, in his discovery of a new element; of Profs. Newlauds, Wilde and others, in their ingenious classifications of the elements by periodic lawe; and of Loutin, Rapieff, Jablochkoff, Werdermaun and Sawyer.

On taking a general survey of the scientific work of the year now closing, all interested in real progress must view with satisfaction the marked change in the tone of scientific eommunications and work. No longer the discussion of remote and wild hypotheses claim the attention of the scientific world; those who rack their brains trying to eolve the probabilities of impossibilities, appear to have fallen to the rear, while *au contraire*, the laboratory and the work shop, are once more proving their utility, and give a healthful tone to scientific inquiry and discovery. JOHN MICHELS.

New York, Dec. 30th, 1878.

THE Carson papers report ex-Governor L. R. Bradley as seriously sick with hemorrhage of the lungs.

THE Japanese are apprehensive that Russia intends to annex Yesso.

Science Bearing on Rainfall.

Mr. Lemmon, in his article describing "Scenes in the High Sierra, back of Yosemite," this week (page 34), speaks lovingly of the glaciers, and of the ice, the sight of whose cool grssn edges has done good to his, and to many another mountain tourist's eyes. Studying the retreat of the glaciers, he sighs at the thought of the torrid and moistureless air melting still further away the few short glaciers that are left in the Sierra, to their sources.

Which brings up the question whether we have not turned the corner in the eosmic economy, and are already having an increase of rainfall, and, of course, snowfall, in the mountains, with its accompanying *neve*, and its ice packing, where the conditions for glaciers exist. This matter came up before ths Geological Sscion of the Academy of Sciences, at its last mesting, on Saturday, the 11th inst—a full report of which will appear in the MINING AND SCIENTIFIC PRESS,—and was very ably discusssd by Joseph Le Coute; Clarencs King's foundation for believing in that hypothssis bsing cited along with other interesting facts, by the participants in the discussion.

In our next issue Mr. Samuel Purnell begins a ssries of several articles in which he will tell our readsrs what is known about the sun-spot cycle of 11 1-9 years, in connection with ths rainfall of the coast. Geological and astronomical science have both established in these linss of investigation, a most practical bearing.

Life Insurance.

The John Hancock Mutual Life Insurance Company of Massachusetts, has lately established an agency for the Pacific coast at 417 California street, under the management of J. S. Byington. This gentleman is highly recommended to us by trustworthy frieuds at the East, and we call the attention of those eeeking life insurance to his company. It will doubtless obtain its share of the business done in this line on this coast. It is well known that the Massachusetts laws governing life insurancs, in certain important features, are in advance of those of other States, as for instance in protecting the insured against nnjust forfeiture of policies. The following quotation from the circular of the John Hancock Co., in a measure explaine this feature:

"The theory of the Massachusetts law is to give each policy-holder the benefit of this overpayment, *without any action on his part, and as a matter of right secured by law*, by continuing the policy in force beyond the date of lapse, until the annual cost of insurance has exhausted the reserve accuuulated while the policy was in force. In other words, insurance is guaranteed by the laws of the State at natural, term, or actual cost-rates, for all the money paid on any policy issued by a Massachusetts company.

"In practice, 20% of the net reserve at date of lapse is withheld, by the law, as a fair allowauce for the future expenses chargeable to the policy; and the remainder, or 80%, is applied to pay for the continuance of the insurance at term rates. If death should occur during the term over which the policy is continued in force, the whole amount insured at the date of lapse, less 'the amount at 6% per annum of the premiums that had been forborne at the time of death,' and all dividends accrued on the policy, are paid the heirs. It is better than a contract, because the language of the Statute is clear and explicit, and not liable to judicial construction adverse to the rights of the policy-holder."

THE DUTY OF THE HOUR.—Lest any reader should forget it, we mention the peculiar fitness of the season for renewing old subscriptions and making new ones to the PRESS. In going forward with our journal, we need the help of our patrons both with mind and money. Do no forget to send the printer his due, as tbe aggregate of small individual amounts will give him a force that will make tbe types fairly dance into the lincs. We trust that only a hint will be needed to rally the dollars, for with them assured we bave a thousand themes to occupy our columns. Let all step up promptly to the Captain's office and tben we will go out on deck for another year's voyage —*January 1st, 1879.*

FRESH attractions are constantly added to **Woodward's Gardens**, among which is Prof. Gruber's great educator, the Zoographicon. Each department increases daily, and the Pavilion performances are more popular than ever. All new novelties find a place at this wonderful resort. Prices remain as usual.

SETTLERS and others wisbing good farming lands for sure crops, are referred to Mr. Edward Frisbie, of Anderson, Sbasta County, Cal., who has some 15,000 acres for sale in tbe Upper Sacramento valley. His advertisement appears from time to time in tbis paper.

EXAMINE the accelerative endowment plan, as originated by the Mutual Benefit Life Insurance Co., of Newark, New Jersey. Assets, $30,533,429.94. Lewis C. Grover, President; L. Spencer Coble, Vice-President; Benjamin C. Miller, Treasurer; Edward A. Strong, Secretary; Bloomfield J. Miller, Actuary. Send for circulars to James Munsell, Jr., agent of insured, 224 Sansome St., San Francisco.

ARTESIAN WELLS WANTED.—Parties wbo are prepared to contract for boring artesian wells are invited to send terms to Edward Frisbie, proprietor of tbe Reading Ranch, Anderson, Shasta County, Cal.

EXPERIMENTAL MACHINERY, drawiugs, patterns, models, all kinds of electrical and telegraphic apparatus to order. See ad. F. W. FULLER, 415 Market St., second floor, S. F.

HENRY R. EWALD is our general eorrespondent and agent for Arizona.

Chew JACKSON'S BEST Sweet Navy Tobacco

Mining and Other Companies.

Cherokee Flat Blue Gravel Company.—

Location of principal place of business, San Francisco, California. Location of works, Cherokee Flat, Butte County, California

Notice is hereby given, that at a meeting of the Board of Directors, held on the 24th day of December, A. D., 1878, an assessment (No. 40) of five cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the Company, 318 Pine street, Room 6, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 28th day of January, 1879, will be delinquent, and advertised for sale at public auction; and unless payment is made before will be sold on Tuesday, the 18th day of February, 1879, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors. R. N. VAN BRUNT, Secretary

Office, 318 Pine Street, Room 6, San Francisco California.

Mariposa Land and Mining Company of

California.—Location of principal place of business, San Francisco, California. Location of works, Mariposa County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the tenth day of January, 1879, an assessment (No. 15) of One Dollar per share was levied upon the capital stock of the corporation, payable immediately in U. S. currency to the Secretary, at the office of the Company, Room 33, Nevada Block, No. 309 Montgomery St., San Francisco, Cal., or the Assistant Secretary at the office No. 9 Nassau St., New York, N. Y.

Any stock upon which this assessment shall remain unpaid on the twelfth day of February, 1879, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on Wednesday, the twelfth day of March, 1879, to pay the delinquent assessment, together with cost of advertising and expenses of sale. By order of the Board of Directors. LEANDER LEAVITT, Sec'y.

Office, Room 33, Nevada Block, No. 309 Montgomery St., San Francisco, Cal.

Mineral Fork Mining and Smelting Com-

pany.—Location of principal place of business, San Francisco, California. Location of works, Big Cottonwood District, Salt Lake County, Utah Territory.

NOTICE.—There are delinquent upon the following described stock on account of assessment (No. 1) levied on the 31st day of October, 1878, the several amounts set opposite the names of the respective shareholders, as follows:

ROOT TEA

Is without a parallel in medicine. The most important discovery ever made in any age or country. It is the only perfect Liver and Blood Medicine ever known, has a powerful and heretofore unheard of influence on the circulation, and is extremely desirable in all forms of debility, local or general, and weakening and wasting diseases, effecting many astonishing cures when all else fails. It effects permanent cures of Blood Diseases which all the old Blood Medicines and the most powerful drugs fail to touch. A continuous influx of testimonials are daily pouring in from all sources.

Mrs. Lydia Read's Cure.

SAN FRANCISCO, January 13th, 1879.

DEAR SIR:—I feel it my duty to inform you what the California Root Tea has done for me, and think you ought to publish it for the benefit of others. I had been failing in health for years, and in spite of all the different treatment I underwent and medicines I swallowed had sunk so low that I could hardly walk across the floor, and felt that my time had come. When in this condition a few weeks ago the California Root Tea was recommended to me by a friend and I began its use. Its effect was most astonishing; it seemed *to actually build me up* from the start, and I am now as strong and hearty as ever. I am confident and so are my friends that had it not been for the California Root Tea I should now be in my grave. [Signed] MRS. LYDIA READ, 1843 Howard Street.

NOTE.—Mrs. Read's complaint was impoverishment of the blood, feeble circulation and a steady and persistent decline that defied the best physicians. For many such complaints there is no possibility of cure with anything heretofore known in medicine. Mrs. Read has resided at her present home for years, and is well known throughout the city as a lady of education and high standing.

The CALIFORNIA ROOT TEA is sold in packets, in its vegetable form. Each 50 cent packet makes a pint of balsam; dose, 2 spoonfuls 3 times daily. Any child prepares it in 10 minutes. Directions inside each packet.

All respectable Druggists and Grocers throughout the country sell it.

PALACE RESTAURANT

218 Sansome St.

This elegant and spacious Restaurant has been re-opened, with Good Living superior bill of fare daily, at 218 Sansome Street, S. F., and is now the best and Reduced Prices most popular dining saloon on this Coast.

[Lunch ready at 10 A. M.] Resident business men and visitors from abroad will be wise in giving this place an early call. Examine bill of fare and prices.

HERMAN H. HORST, Prop'r.

DEFLECTED HEAT!

Boswell's Combined Heater, Cooker, Baker. Clothes and Fruit Drier.

Combining the advantages of a Stove, Furnace, Oven, Dry House and Kitchen Range. An application of Scientific Principles to the economy of living, of labor, of health and of comfort. A handsome piece of Furniture adapted to the wants of every family. It equally economizes time, labor and fuel, and avoids exposure to heat in cooking as well as in baking. It bakes Bread, Cakes and Pies to any desired tint without turning or watching, or danger of burning. All odors produced in cooking are passed up the flue. Food cooked by deflected heat is improved in flavor, more easily digested, contains more nutriment, will keep fresh longer, and is also much improved in appearance. The stages of the cooking or baking can be seen without stooping or opening the doors of the oven. It will dry and bleach your clothes in from half an hour to one hour and a half, and heat your irons.

Fruit dried in the Boswell will gain from TWENTY to FORTY PER CENT. in WEIGHT, and THIRTY PER CENT. in QUALITY over that dried by any other process. It will successfully dry any kind of Fruit, Grapes, Berries, Meats, Fish, Vegetables, Coffee, Tobacco, Corn and Grain of all kinds.

— ALSO —

Boswell's Commercial Fruit Drier,

Used exclusively for drying and heating purposes ON A LARGE SCALE.

— ALSO —

BOSWELL'S CABINET HEATER,

Of all sizes and capacity for heating Private Residences, Hotels, Halls, School Houses, Churches, Offices, Stores, Railroad Cars, Hospitals, etc.

All of which can be operated successfully by a mere child, it is so simple in its construction, and with one-third the usual amount of fuel (coal or wood), used in any other heating, cooking or drying apparatus.

Every farmer and economical housekeeper should use it. It will pay for itself in the saving of fuel; it will pay in the superior character of its FRUIT DRYING, of its COOKING, ROASTING and BAKING; it will pay in its salubrious and healthful warm air; it will pay the rich and the poor alike.

Address, for Price List and descriptive illustrated circulars,

Boswell Pure Air Heater Co.,

No. 606 Montgomery Street, San Francisco, California.

Paul's Pulverizing Barrel.

ALMARIN B. PAUL.—*Sir:*—Your Pulverizing Barrel I am much pleased with. It seems to combine all the requisites for cheaply reducing quartz to any degree of fineness desired. As a mat hine for preparing ore for the LIXIVIATING PROCESS, it certainly is a most perfect one, from the fact that it will deliver the ore, in granulated form, no matter how fine it may be desired to have the grains, thus allowing rapid percolation of the dissolving liquid. Working in connection with crushers as I have used it, it certainly is ahead of any stamping machinery.
J. O. STEWART.

MINING AND SCIENTIFIC PRESS.

An Illustrated Journal of Mining, Popular Science and General News.

BY DEWEY & CO., Publishers.

SAN FRANCISCO, SATURDAY, JANUARY 25, 1879.

VOLUME XXXVIII Number 4.

The Little Wonder.

We illustrate herewith a self-calculating sample and button weigher, for prospectors and assayers' use, a patent for which has just been obtained through the MINING AND SCIENTIFIC PRESS Patent Agency, by Mr. J. S. Phillips, the well known author and mining engineer of this city. It is a combination in one device, of weighing scales, balances, weights, forceps, calculating tables, or scales, by which the inventor provides a simple and ready apparatus, with which the prospector can accurately determine the dollars per ton in gold and silver, as well as the fineness and percentage. It is well named "The Little Wonder."

The stand or case is made of metal, and has an open top and ends. Across the center is an upright gripping piece, in which is an inverted knife edge, on which the beam is balanced. This metal beam has at one end and forming a permanent part of it, a conical platinum cup, and at the other end a small knife-edged crook, on which may be hooked a little pan. To balance this aluminum pan when attached to the crook by a hook and silk cord, a balance-clasp is put on the beam. This clasp is shown snapped on to the forceps ready for use. When balanced by the clasp the pan can be used for weighing the sample bullion, and buttons in the usual manner.

On the back of the case are two lugs, *L*, which hold the beam in position, when it is not in use. The knife-edge, on which the beam rests, extends to the back of the case; and by sliding the gear back and slightly springing the ends under the lugs, it is held firmly in place. The gudgeon piece or inverted knife action is shown in the center of the beam. The weights for use on this beam are made in the form of riders, and are kept in the weight case, *W*, which has a cover, as shown, to keep them in place. On the beam is fitted a permanent adjunctory or regulating paper disk weight, which may be slid back or forth. The riders or weights are of different colors, for easier discrimination.

On the inside of the case, under the beam, is placed a scale, marked or printed on paper with properly marked cross lines, which in combination with the different colored and weighted riders, will give the value in gold or silver bullion in dollars and cents, without the necessity of figures or any calculation whatever on the part of the operator, who is not even required to read figures as none are used.

The front part of the stand is turned over to form a circular hollow side, inside of which is placed the large bar weight, used as a balance for samples of ore. The heavy beam is made semi-tubular at its center, and on its closed side is made a diamond-shaped slot (shown in engraving) by which the beam is kept in proper position on the knife top when in use. Two large pans, *P*, are used with this beam and are suspended from its ends by hooks and silk cords. This beam is used for weighing samples of auriferous quartz and large silver assays. These pans have only two sides, which when not in use fit under the stand or case, the sides projecting upward as shown, so as to encircle said case. The three weights used with these pans are made of different sizes and colors. They are made of wire rod bent into S C shape, indicating that they are self-calculating weights. These are used for weighing the samples to be assayed, the resultant button being weighed on the other beam by the other weights as described.

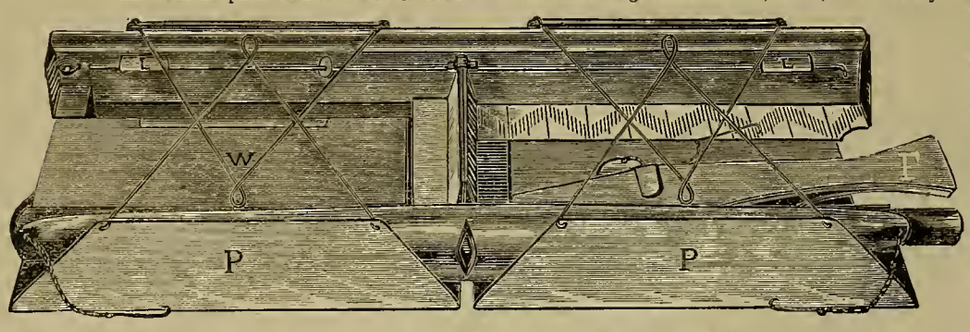
By weighing a sample of bullion or base metal ore to equal either of the riders, or any other quantity, by a rider-shaped weight, the thousandth fine of such metals, or percentage of such ores may be known at sight after cupellation or reduction, by simply placing each of the several resultant buttons in the cup, and sliding the same rider to correct the balance upon the other end of the beam opposite the appropriate scale.

It will be readily seen that by taking suitable quantities as provided by the large yellow bar for gold, and the yellow S C weight for silver, not only the percentage and thousandths fine may be obtained as above, but also the value in dollars per ton for gold and silver, the same scale being common to all fire methods of assaying.

This device is extremely portable, the beams, weights, pans, pliers, all fitting together, as shown, so as to be slipped in a small box and put in the pocket. It affords a portable, convenient, self-calculator, and exceedingly delicate weigher of minute buttons, and such assays may be made with very great accuracy. But it may also be used for furnace assay buttons, either by its self-calculation or the scale, or for those who may prefer it, by attaching the pan and weighing by any decimated weights in the pan itself, which may still be read under the self-caculating mode or by any more ordinary manner.

Being entirely portable, delicate and efficient, this apparatus is of great use to prospectors as it does away with the necessity of expensive balances which occupy considerable room and require care and skill in management. This apparatus contains all that is required for such simple assays as prospectors need to make, and obviates the necessity of any calculations being made, the weights, as described, being self-calculating. It is specially devised for blow pipists.

The illustration is full size, and the price of the whole apparatus is $25.



PHILLIPS' SELF-CALCULATING SAMPLE AND BUTTON WEIGHER, FOR PROSPECTORS.

PACIFIC COAST CONE-BEARERS. — We begin this week the publication of a series of articles on the cone-bearers of California, written for the PRESS by Prof. J. G. Lemmon, of Sierra Valley. Prof. Lemmon is well known to our readers as a botanist of high standing, and as a writer whose love of nature, brilliant imagination and warm heart lie near his pen point and give a glow to all his composition. The series which we now have in hand will be found of a more popular character than the essays on the subject, by Prof. Asa Gray, which we published last summer. They will, however, be no less accurate as scientific reviews of the subjects advanced. Prof. Lemmon has lived for years among the trees which he presents to his readers, and has studied them as familiar faces. To be sure of his accuracy on scientific points, the series has been examined by Dr. Engelmann, of St. Louis, who leads the van in this branch of botany. We trust that all our readers who are interested in trees (and who is not?) will study this series of articles carefully and acquire an accurate knowledge of this division of local botany, which will be always of educational and practical advantage to them. Prof. Lemmon does public service by his writings of this kind, and we trust his reward for his honest work will come in due time, from the pockets, as well as the hearts of the people.

THE London and San Francisco Bank has received a telegram from its London correspondent, announcing that Lawrence O. Hall, the absconding clerk who got away with about $40,000 of the bank's money, was arrested on the steamer *Oceanic*, but whether at Yokohama or Hongkong the dispatch does not state.

THE United States sailing ship *Constitution* went ashore the other day on the English coast.

Copper Metallurgy.

Mr. Tulio Ospina, a student of the College of Mining of the University of California, proposes a modification in the precipitation of copper, by means of iron, in its extraction by the wet process, to be applied when the precipitating iron is in the shape of filings or *iron sponge*, for the purpose of avoiding the mixing of the fine iron with the copper precipitates.

The process consists in packing the iron into bags before putting it into the copper solution. It is based on the principle that the precipitation is effected in an electrolitbic way—a fact that Mr. Ospina has proved conclusively by the following experiments:

He packed some iron in a linen bag, with a piece of copper wire, in such a way that only a part of the latter would project outside of the bag. This having been placed in a solution of sulphate of copper, a thick layer of copper was deposited on the copper wire.

A similar arrangement, but in which the copper wire was isolated from the iron by a piece of glass tubing, remained in the solution till all the copper was precipitated on the linen, while there was none on the wire.

The precipitation, when effected in the proposed way, takes of course longer time than if it were effected by uncovered iron; but not so much longer as it would seem at first sight, on account of the precipitation being electrolithic.

Experiments made with bags of different kinds of materials gave the following results, as to the amount of copper precipitated inside of the bag, and the relative time of the precipitation:

Number of Threads per Centimeter of the Staff.	Percent of Copper Precipitate inside of the Bag.	Length of Time Required for the Precipitation.
12	3.1	5h 45'
18	2.6	6h 50'
31	2.3	8h 2'

The precipitation has to be made at a high temperature, and from a solution not exceeding 12° B, in order to obtain a loose precipitate, that can be easily detached from the bag. To make this, a canvas made of well-twisted threads is to be preferred.

The applicability of this process, as that of all the metallurgical processes, depends on local circumstances; but so far, we do not see why it could not be used in the localities where only *iron sponge* is to be had as a precipitating agent for copper, with the advantage of saving, by the use of some more time and fuel, the expense and trouble of refining the copper when it is mixed with a large amount of iron.

OUR series of articles on the quicksilver mines of old Almaden are concluded with a showing of the total product from 1564 to 1875, amounting to 120,000,000 tons in weight. *Apropos*, is the present value of quicksilver, for a graphic representation of which we are indebted to a fluctuation profile prepared by Mr. J. B. Randol, covering the period from 1850 to 1877. The price was lower in 1877 than ever before, during the period mentioned, except in 1861 and 1862, averaging between 40 and 50 cents per pound.

Academy of Sciences.

The regular meeting of the Academy of Sciences was held on Monday evening last. Dr. Blake read a paper on "The Rainfall in Different Parts of the State." It was shown that nearly all points on the coast receive more rain than San Francisco. The largest fall last year was at Truckee, viz., 87½ inches.

Dr. Kellogg read a description of a Japanese plant, purporting to be a superior substitute for asparagus, cooked and eaten in the same way. The seeds of this plant had been brought from Japan, but it had been cultivated here by Dr. Kellogg and Mr. Harford, successfully, and the specimen of the plant exhibited was that raised here.

A paper upon the "Genesis of Cinnabar Deposits" was read by S. B. Christy. The purpose of the paper was to determine whether cinnabar deposits were formed, as is usually supposed, by volatilization or from solutions. In the first place, the most noted cinnabar mines were briefly considered, and that of New Almaden was minutely described. Second, a brief statement of the chemical properties of cinnabar, as at present known, was given, showing that the present state of knowledge was insufficient to explain the formation of cinnabar in the wet way. Third, the results of some original experiments made by the author at the University of California were described. These experiments were undertaken at temperatures of from 150° to 250° Centigrade, and at pressures of steam of from 200 to 500 pounds per square inch. The results showed that cinnabar was soluble in the alkaline sulphides under these circumstances. The author succeeded in producing artificial cinnabar similar to that which occurs in nature. Also from the New Almaden Vichy water by adding sulphydric acid, in a similar manner, cinnabar was produced. Fourth and lastly, the author discussed the relative probabilities of the rival theories, and showed by a preponderance of evidence that the deposits of cinnabar, as they exist at present *in situ*, are undoubtedly the result of deposit from solution in solutions of the alkaline carbonates.

Prof. Davidson expected to have read a paper "On Instruments of Precision," but illness prevented his attending the meeting. The paper will probably be read at the meeting on the first Monday in February.

Tricks that are Vain.

We have been favored with another example—from Mr. J. S. Phillips, M. E.—where a peculiar method of salting had evidently been used. It consisted in dissolving an ordinary amalgam of silver and mercury in sulphuric acid, dipping porous sand-stones in the solution, and then disguising the excess of acid by ammonia.

The suspicious character of the stones and the peculiarly precious story of a mile square of such high ($500) average rock, induced the intended victim to seek chemical aid, which exposed unnatural quantities of sulphur, quicksilver, and even ammonia.

Subsequent examination of the so-called valuable property led to its condemnation, as none of these substances were found on the extensive scale described, in otherwise similar natural formations.

AN organized raid has been made by the Los Angeles police on the Chinese opium dens, and for the first time a law is found to fit their case. These places will now probably be entirely broken up.

SECRETARY SHERMAN, on Saturday, called for redemption $20,000,000 of 5.20 bonds of 1865, consols of 1867.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

About the Snake River Gold Mines.

How to Save the Gold.

Editors Press:—In reference to the Snake river country I will give you what I know to be facts, partly from personal observation and from information gathered from reliable parties who have but recently returned, among them Prof. J. E. Clayton. You say that many people at the Bay think the Snake river reports a humbug, and got up in the interests of traders, etc. This is quite an erroneous opinion. I have had men in my employ for years who were prospecting that stream in 1870, following it up from Taylor's bridge for 400 miles; they reported then finding gold all the way up, but so fine that they could not make wages with pan and rocker, but used amalgamated copper plates, then making high wages. They did not prospect then for *lodes* or *veins* bearing gold, but followed up the stream for coarser placer gold, that could be saved in the sluices. They were not prepared at that time, to try the plates as thoroughly as they are used now, but used quicksilver in riffle boxes. They reported finding hars where they could make four and five dollars a day to the hand on the average, and sometimes $30, $40 and $50 per day, but were much harassed and troubled by Indians attempting to steal their stock.

The whole valley and river bottom is frequented by the Snakes, Shoshones, and other tribes, for fishing purposes. The stream affords any amount of sturgeon, salmon, and various kinds of fish. The sturgeon are very large, some of them weighing 150 pounds. Though supposed to be friendly, the Indians of this region have always shown a disposition to annoy small parties.

The river bottom is not a continuous valley. In many places it runs through barren sage brush plains; in other portions through beautiful fertile valleys. But little timber is found, except cottonwoods upon the immediate banks of the river, until it turns north towards the Columbia, and above the first canyon. This is situated 30 miles or more above Taylor's bridge, and is 25 miles long.

Most of the mining was done in '70 and '71, below the bridge. The bedrock there, is a lava rock; and the gold on the bars is in sand with fine shells, but very little clay is found. Above the canyon there are extensive gravel beds 50 feet high, showing cement gravel where the river has changed its bed, good gravel claims will no doubt be found. Above this the stream forks into the north, middle and east forks. On some of these good hydraulic claims were opened several years ago, and it is said coarser gold was found on some of the branches.

That it is a gold country for 400 miles along Snake river, does not admit of a doubt. If there are any traders to be benefited by reports, they have established themselves lately, and since we passed through the country in '71. It is a good stock range and a great game country, ducks, geese, deer, antelope and hare are plentiful along the whole stream. That portion of it now being prospected, runs through several detached spurs of the Rocky and Blue mountain ranges. These canyons are steep, rocky and hard to penetrate with animals. Here of course, there is plenty of fall, but very little chance to get at the river bed. Outside of these gorges where the river spreads out and forms bars, there is but little fall and water. To get any considerable head, water will have to be brought long distances—if indeed that is practicable, on account of the sandy nature of the soil. Doubtless gold will be found in the vicinity of small branches and the canyons above referred to, where water may be obtained without pumping it from the river.

The Present Method of Saving the Gold

Is simply adapting the mill process of saving the gold outside of the batteries; and parties succeed who copy this process as nearly as possible, provided always that there is plenty of gold to save.

I read with much pleasure the opinions of Messrs. Attwood and Paul, on gold amalgamation, rusty gold, etc. They are both gentlemen of long practical experience, and their ideas tally with the settled convictions of a large majority of old miners and millmen. Ask them to explain through your columns, why it is that gold scraped from a retort will not readily amalgamate. Such is the fact; sometimes a little adheres to the bottom when the retort has been overheated; on chipping this off it is difficult to make the gold amalgamate with clean quicksilver. I often thought of trying to ascertain the cause, but never attempted to do so; and it is now several years since I have had the opportunity. Mining in this section is confined to silver and galena ores.

In conclusion, without going minutely into the details of gold amalgamation, I will say in general terms, the slower the gold can be made to pass over the plates, the more will adhere to them. It is scarcely necessary to say the more perfectly the gold is freed from clay, sand and all other sticky gangue matter, before it reaches the plates, the better; for the reason that if much remains you must either use a large head of water, or set the plates steep; either of which is against close amalgamation. In placer mining the gold is nearly always mixed with more or less clay. It is absolutely necessary to free the gold from this before its reaches the plates. To do this it often requires a large and swift head of water in the sluices. The sluices should be sufficiently long to have the clay forked back until completely torn to pieces, and dissolved, so that nothing but riley water passes over the plates. Before the rush of water reaches them, make a quicksilver trap; a box six or eight inches deep between the last sluice and the plates. In the center of this, crosswise of the sluice, a gate. Put an inch of quicksilver in the box and push the gate down close to it, so that everything goes down on the upper side of the gate, into the silver, and up on the lower side into the amalgamated plates—having taken a quicksilver bath. Below the trap a table should be used much wider than the sluices, and the water spread over it by stops and cleats, with just force enough to clean them of sand. Keep the amalgam as soft as it may be without breaking and running off the plate. Use rubber belting to scrape your plates, and do not scrape to clean at first; have plenty of amalgam on them, you will not lose by it. Truly yours,

"'49ER."

Park City, Summit Co., Utah, Jan. 1st, 1879.

Undercurrent Wheels for Hoisting and Washing Gravel.

Editors Press:—Much has been said and written in the Press about dip wheels and their uses. Such a wheel has been erected this summer on Poverty Bar, on the middle fork of the American river, Placer county, California, by five workingmen, no other capital except their labor and brains, combined with indomitable will; they deserve much credit for their energy and perseverance. The wheel is doing excellent service, and they are being amply rewarded for their labors by working a fine claim, which is paying well.

The size of the dip wheel is 48 feet diameter and 8 feet breast. The buckets are 15 inches wide on each side of the wheel. It lifts 125 inches of water 48 feet, and discharges it into a ditch 500 feet long. This water is the power for hoisting the dirt with a derrick and pumps the water over 25 inches. The pit is 40 feet deep.

The latter wheel is 29 feet diameter, 4 feet breast. They raise about 30 cars per hour; each car weighs 1,400 pounds. This water is also used to wash the dirt, and there is plenty of water for all purposes.

Now will any of your readers tell us how much water (miners' inches) it requires to run the big wheel, and lift from 125 to 175 inches of water 48 feet?

By giving this a place in your valuable paper you will much oblige a constant reader.

John Hemsley.

Cosmic Meteorology.—No. 1.

[Written for the Press by Samuel Purnell.]

Some of the readers of the Press may remember that about a year ago a series of articles was published over my signature on "Trees and Rainfall," in which it was attempted to be shown how summer rains can be produced in California. The lapse of a year has further convinced me as to the soundness of the views therein expressed, to the effect that a considerable rainfall could be induced during the hot months of summer by the maintenance of trees. In one of the articles some reference was made to the recently-arisen question of the relation of

Sun-spots and Rainfall,

And the extreme probability of the amount of rainfall upon the Pacific coast of the United States being dominated by the 11 years sun-spot period; also that, as the year 1877 was one of a minimum sun-spot group, I considered it probable that the ensuing winter would be what is locally known as "dry;" that is, a winter when the average rainfall throughout California is not sufficient to secure fair crops throughout the State. Inasmuch as nearly twice the annual average of rain actually fell, the failure of the prophecy hazarded, was so complete as to be almost ridiculous. The grounds of this supposition were, in brief, as follows: That as all terrestrial motion depends upon the sun, more or less activity of the sun will cause more or less activity in the motive powers at work upon the earth; that after many years of observation it has been ascertained that the activity and dynamic qualities of the sun vary from year to year, and in a cycle averaging eleven and one-ninth years; and that this variation is coincident with, and more or less dependent upon, the increase and diminution of the sun-spots; that when the surface of the sun is thickly covered with spots, its potency is enormously magnified, and the solar forces which govern all terrestrial phenomena are correspondingly exalted; that during the period of minimum sun-spots the activity of the sun is greatly lessened, as shown by the insignificance of the chromo-sphere, the prominences, and the corona; that while the whole scope of the power and influence of sun-spots, or of that solar condition of which they are indicative, is not much understood, yet enough is known to strongly affirm that the potency of the leading terrestrial physical phenomena advances and recedes as does the quantity of the sun-spots; and that a cycle of magnetic declination, of *aurorœ polares*, of cyclones, of temperature, and of rainfall exists coincidently with, if not completely governed by, the sun-spot cycle; and that while the winter rainfall of California did not, as yet, exhibit exact accordance relatively with the sun-spot curve, it appears to be chiefly influenced by the varying solar state, the maximum and minimum of rainfall generally occurring in the maximum and minimum sun-spot year-groups respectively; and that there can be little doubt of the truth of the broad assertion that, taking the entire surface of the earth, the totality of the rainfall is strictly variable relatively with the solar spots.

But the time for prophecy has not yet come; knowing the law of the totality of rainfall, its local distribution is but feebly understood, and cannot be predicted. Why, in 1877–8, a year of the minimum sun-spot group, California should have received a maximum rainfall, I do not know, have no means of knowing, nor do I know of any one who will venture a theory upon the cause. Evidently, there is much yet to be ascertained before the rainfall of any particular place can be confidently and scientifically predicted far in advance; but very much, indeed, has been accomplished when one is able to say that the totality of rainfall agrees with the variation of a well-known heavenly phenomenon; and

The Day will Come

When cosmic and terrestrial meteorology will each be so thoroughly understood that the local rainfall of California, or of any other State, can be accurately predicted many years in advance. When this, now intricate and insoluble problem is mastered, the coming man will have learned how to produce rain.

Although the rainfall for 1877–8, upon the Pacific coast of America, was so largely in excess of the indications, yet the influence of the minimum sun was remarkable in many other parts of the world, and the moisture that should have fallen upon their drouthy lands, was instead poured upon this coast. From Alaska to the equator the Pacific coast received, with some exceptions, from one and a half to three times its mean annual rainfall, and most of the entire continent of North America and western Europe is reported to have received more rain than upon the average. In contradistinction to this,

Australia,

In the summer of 1877–8, suffered a severe drouth; the famine of India still continued; northern, China experienced a drouth and resultant famine that cost millions of lives; the Sandwich islands and other Pacific islands suffered from an unprecedented drouth; Brazil encountered her most disastrous drouth of the century; in the northern States of Mexico a drouth and famine prevailed to such an extent that provisions had to be imported; in New Guinea the natives suffered frightfully from a drouth; a drouth that caused the failure of crops prevailed on the western coast of South America; Persia and the central plateaus of Asia were also devastated by drouth; and, no doubt, when the returns shall all be made up, it will be seen that upon the whole, the rainfall of the last season was largely below the mean. Thus it will be seen that there were weighty reasons for the belief that California would, last season, meet with a "dry winter;" and why it did not, will in the future appear from the law of variation, to be discovered.

It will be interesting to examine briefly the

Literature of Sun-Spots

And their correlative manifestations; to look into their cause, nature and character, their periodicity, the like and almost equal periodicity of magnetic variation, of cyclones, of aurora polaris, of hurricanes and marine losses, of epidemics, of disease, and of drouths and rainfall.

The literature of sun-spots commences with the dawn of history. In very ancient times black spots upon the face of the sun were, of course, observed when large enough to be seen by the unassisted eye (?) They are supposed to be mentioned in the first Georgic of Virgil. The Chinese recorded the appearance of sun-spots A. D. 321; and Acosta says the natives of Peru told the Spanish invaders that the sun's face had, in former times, been marked with spots. In the year A. D. 807, a large spot was seen on the sun for eight successive days. In 1611 the first scientific observations upon the spots were made by Fabricius; and soon after Galileo began to study them, pursuing the subject with such diligence that he lost his eyesight. But no systematic observations were made till Hofrath Schwabe took up the subject in 1826, who, after about 12 years' labor, first recognized their periodicity. It is almost needless to say that no one believed his report. He then labored on for 20 years more, till he had completed the observation of three complete oscillations from maximum to minimum and back again, during which time he made about 9,000 observations and discovered 4,700 groups of spots. It was principally from a study of Schwabe's observations that Prof. Rudolf Wolf, of Zurich, deduced the periods of oscillation as 11.11 years. Schwabe's observations were improved upon by Mr. Carrington, of England, and by Dr. De la Rue and Prof. Balfour Stewart. Dr. Wolf has published a list of the mean relative number of sun-spots for each year from 1750 to 1877. Although somewhat inaccurate for those years prior to 1820, when Schwabe began his exact observations, this list exhibits 11 cycles of sun-spots, giving an average of 11 1-9 years to each cycle.

These Cycles

Of solar activity have been proved to be coincident and correlative with several well marked cycles in the atmospheric and other conditions of the earth, attention having been chiefly given to the correspondence in four particulars: 1st, periodical variations in terrestrial magnetism and electrical activity; 2d, periodical variations in temperature; 3d, the periodicity of wind disturbances, hurricanes and cyclones; 4th, the periodicity of the total rainfall.

In the condensation of the facts of the several discoveries and publications upon these subjects, as given below, I am chiefly indebted to the admirable resume of the whole subject by Messrs. J. N. Lockyer and Dr. W. W. Hunter, in a late issue of the *Nineteenth Century*.

1. With regard to the

Sympathetic Periodicity

Of terrestrial magnetism and electrical activity. The magnetic needle, though seemingly still, is yet always in motion. Certain of these motions depend on the hour of the day; others on the rotation of the sun, moon, etc., but the magnet is liable to irregular and abrupt fluctuations which cannot be connected with the daily oscillations. Sir Edward Sabine found that such fluctuations are most frequent in years of high sun-spot activity, which relatively had been suggested as far back as 1785. Gauss made further discoveries between 1834 and 1837. Arago's observations from 1820 to 1830, published in 1854, further established the relation. In 1851, Dr. Lamont published his long-continued researches, indicating the existence of a cycle of magnetic variations, occupying, as he believed, on an average 10½ years. Sabine in 1852 carried on the work still further, and be observed that the irregular fluctuations of the magnet were almost invariably accompanied by displays of the *aurora polaris*, and concluded that auroral displays occurred most frequently in years of maximum sun-spots, a conclusion which has since been completely verified. Dr. Wolf and M. Gautier had independently remarked in 1852 the coincidence of the decennial magnetic period with Schwabe's period of sun-spots. In 1865, Prof. Loomis, of Yale college, supplied further evidence on the range of the magnetic declination and auroras in their relations to sun-spots. He concluded that the auroras observed in Europe and America exhibited a true periodicity, closely following the magnetic periods. Signor Schiaparelli, in 1875, made important contributions to this subject, as did also Sophus Tromholdt in 1875, and Dr. J. A. Brown in 1876. The latter gave the mean duration of the magnetic cycle at 10.45 years, and he supplied a valuable chart showing the decennial period of the diurnal range of the magnetic declination and the sun-spot area from 1784 to 1876. The curves show the general coincidence of the magnetic and sun-spot cycles in a clear light. In 1877, Prof. Balfour Stewart reviewed the whole question, and exhibited the sun-spots, magnetic declination, and auroras from 1776 to 1872 in curves which follow each other with indisputable coincidence. He further examined the connections of these three coincident cycles with the planetary configurations, the result of which will be stated further on. It has been observed in England that earth-currents disturbing magnetometers, and telegraphic instruments are in close relationship with auroras and sun-spots; and that magnetic storms occur most severely during periods of maximum sun-spots. "To sum up," says Lockyer and Hunter, "magnetic observers now hold that not only do the spasmodic fluctuations of the needle follow closely, curves coincident with the sun-spots, but its diurnal oscillations are not less dependent on the state of the sun's surface."

2. With regard to solar radiation and

Thermometric Variations

Many difficulties complicate this line of research, and the evidence is less complete than that which connects the other phenomena mentioned with the sun-spots. The reasons for this will be plain upon a little reflection. The temperature range that must first be had, is that of the universal mean, and this, of course, cannot be obtained till there is a universality of thermometric observations and records. The mean temperature of one locality, or even the average mean of a hundred localities, it is plain can serve, but as a coarse approximation, to the mean total temperature. Unlike the instantaneous and universal operation of terrestrial magnetism and atmospheric electricity, which can be nearly as well observed in one place as another, and almost as completely in one place as in a hundred, heat is, as far as can now be said, altogether local in its appearance, power and duration, and, as is well known, the mean temperature of every locality is an individual quantity, varying from that of its neighbors.

The atmosphere is the scene where the solar energies are incessantly in operation; and when most active, are most screened from the surface. There is evidence to show that the vapor of water, like the vapors of metals, exists in various molecular conditions, some of which are transparent and some are opaque to those rays which affect our thermometers; and, according to Mr. Lockyer, there is evidence to suggest that the aqueous vapor produced at the period of minimum sun-spots would be more transparent to the heat rays than that produced at other times. The thermometric inquiry divides itself into several distinct branches, such as the direct solar radiations, the calorific intensity of the sun's light, the daily temperature range, and the mean annual temperature, all of which must be passed by with slight notice, as this paper is more particularly devoted to the question of the relation of sun-spots and rainfall.

MECHANICAL PROGRESS.

Dry Plumbago vs. Oil in Steam Cylinders.

A correspondent of the *American Machinist*, has been experimenting with the ors of dry plumbago as a substitute for tallow and oils for steam cylinders. The correspondent, who is an engineer of some years' standing, writes as follows: The engine upon which the experiment was tried was an 11x30 horizontal engine; piston speed, 300 feet per minute, and was known as the "West Poppet-Valve, Automatic Engine." It was worked up to its full capacity, and, to insure a fair trial, the existing oil-cup was exchanged for a goblet-shaped tallow-cup with a lid, after which the piston-follower and springs were taken out and cleaned. When ready to start the engine, one-third of an ounce of finely powdered Ceylon plumbago was placed in the cup. As soon as the engine was fairly under way, the valve of the grease-cup was opened half way. After running some time it was opened all the way. When the engine was stopped at noon, the plumbago had all passed into the cylinder, of which there had been strong evidence, soon after starting, as the piston-rod became coated with it. Upon starting up in the afternoon, one-third of an ounce more was placed in the cup, and the engine run until six o'clock, with a similar result. There was no noise in the cylinder, either in the starting, running, or stopping of the engine; and after 18 months' use, with the above-named quantity applied twice a day, no noise has been heard in the cylinder, except when the steam was shut off for the purpose of stopping the engine, when it would be heard during one or two strokes of the piston, just before the engine stopped. This occurred not oftener than would have taken place if tallow or oil had been used. Soon after beginning its use, a portion of the plumbago would be found remaining in the cup; to obviate this, about an ounce of water was poured into the cup, after the plumbago had been put in, when a decided improvement was observed, so much so, that it can now be fed into the cylinder as readily as oil or tallow. After four weeks' use, the cylinder-head was taken off and the working part of the cylinder was found coated with plumbago which could not be easily rubbed off with the fingers; the interior of the piston was found as clean as when it left the lathe, so far as dirt of any kind was concerned, and such is the condition to this day.

GAS ENGINES.—A successful gas engine is something that is greatly needed for many purposes, especially when but small power is required, and particularly on crowded business streets in cities, where the presence of steam boilers are not desirable. Just at this time the Otto gas engine seems to be attracting much attention. At a recent meeting of the Franklin Institute, in Philadelphia, the chief attraction of the evening was the new "Otto silent gas engine," which was placed upon the stage, and, after an explanation of its various parts, as shown upon a screen by the aid of stereopticon, was set to work. It was claimed that for persons requiring a moderate use of power, this motor is the best that could be devised. It is at all times ready for use, either continuously or intermittently; can be started and stopped readily; burns not more than four and a half cents' worth of gas per hour per horse power; is entirely free from the danger of explosion, as no steam is used; there are no coals, ashes, dirt or smoke; costs nothing when idle, and but little when running, and is almost noiseless. The charge of gas (or petroleum) and compressed air burns readily, and the combustion is automatically regulated with very little shock to any of the parts, in proportion to the power developed.

HEAVY RAILS PREFERABLE.—English engineers are fast coming to the conclusion that heavy steel rails are economical. They entertained this belief long ago, and it was based upon scientific reasons. Now that steel is so very cheap, their scientific views are more than confirmed. The Phœnix Bessemer Steel Company are now making exceptionally heavy rails for the Midland Railway Company, the weight being 85 pounds to the yard. A heavy rail like this ensures a smooth run, and adds to the safety of the train. Rails now in course of delivery by the Dronfield Steel Works to the Great India Peninsular railway are 80 pounds to the yard.

IRON AND STEEL.—In the course of his address to the Society of Arts, recently, Lord A. Churchill called attention to the enormous development of the steel manufacture during the last two or three decades. So rapidly, he said, was it taking the place of iron, that an eminent engineer has said the days of iron are numbered, and that 50 years hence it would be unknown.

THE steel product of the whole world 20 years ago amounted to little more than 300,000 tons, at an average cost of about $150 a ton. Last year the production went beyond 2,200,000 tons, and its cost only showed an average of $60 a ton, a falling off in cost of production of 60%.

A NEW COMBINATION RAIL.—The latest device for a rail consists of two outer steel plates, two inner iron plates, with a lead plate between them, and strips of paper between the iron and steel plates, the whole united by bolts.

Making Lumber from Straw.

A person named S. H. Hamilton, of Bushnell, Illinois, has been in this city for two or three days past, with samples of lumber, which has attracted much attention among the lumbermen and which, if it possesses all the virtues that are claimed for it, is one of the most important inventions of its kind ever brought to notice. If it is a success it will form a new era in the art of building. To make hard wood lumber out of common wheat straw, with all effects of polish and finish which is obtainble on the hardest of black walnut and mahogany, at as little cost as clear pine lumber can be manufactured for, is certainly wonderful. Such are the claims of Mr. Hamilton for the straw board lumber which he has been exhibiting in this city, and the samples which he produces would go far toward verifying his claims. The process of manufacture, as explained by Mr. Hamilton, is as follows: Ordinary straw board, such as is manufactured at any paper mill, is used for this purpose. As many sheets are taken as are required to make the thickness of lumber desired. These sheets are passed through a chemical solution, which thoroughly softens up the fiber and completely saturates it. The whole is then passed through a succession of rollers, dried and hardened during the passage, as well as polished, and comes out of the other end of the machine hard, dry lumber, ready for use. Mr. Hamilton claims that the chemical properties hardening in the fiber entirely prevent water soaking, and render the lumber combustible only in a very hot fire. The hardened finish on the outside also makes it impervious to water. The samples which Mr. Hamilton exhibits could hardly be told from hard wood lumber, and in sawing it the difference could not be detected. It is susceptible of a very high polish, and samples of imitation of marble, mahogany, etc., were shown, which might deceive the most experienced eye. Not only does Mr. Hamilton claim a substitute for lumber in sash, doors and blinds and finishing stuff, but also as a substitute for black walnut and other woods in the manufacture of all kinds of fine furniture, coffins, etc., and also an excellent substitute for marble in marble-top tables, mantle pieces, bureaus, etc. He claims that it will not warp in the least. Mr. Hamilton is negotiating with parties here, with a view of establishing a manufactory in this city for making the various articles of building material for which his lumber is suitable.—*Oshkosh, Wis., Northwestern.*

FLINT BRICKS.—Under the title of "Improvements in furnaces and other building blocks, retorts, crucibles, and other fire-resisting articles" a patent has recently been taken by Mr. D. Selwey, of Bridgend, Glamorganshire, for bricks composed of pure flint, without the admixture of alumina or any other substance to detract from the high refractory character of the material. The inventor treats the flints in such a manner as to produce from them, when in a pulverized condition, bricks or blocks of great structural strength and durability, superior in fire-resisting properties, it is said, to the best descriptions of fire-clay goods. His patent also extends to the manufacture of artificial stone for building purposes. The material when burned resembles a fine-grained freestone, and is sufficiently hard to resist the action of the weather. It is in furnace work and similar applications, however, that these bricks are expected to be most successful.

A NEW ROTARY ENGINE.—Mr. Babbitt, the well-known soap manufacturer, of New York, has invented a rotary steam engine, which is said to develop extraordinary power, with a very small steam supply. A correspondent of the *American Machinist* reports having seen one, four inches in diameter, running 20,000 revolutions a minute, with steam supplied by an one-eighth-inch pipe, which defied the efforts of the heaviest men to stop it by throwing their weight upon a good lever.

MALLEABLE BRASS.—A German periodical is responsible for the following method of making malleable brass: Thirty-three parts of copper and twenty-five of zinc are alloyed, the copper being first put into the crucible, which is loosely covered. As soon as the copper is melted, zinc purified by sulphur is added. The alloy is then cast into molding sand in the shape of bars, which, when still hot, will be found to be malleable and capable of being brought into any shape without showing cracks.

AN IMMENSE LOCOMOTIVE.—An immense locomotive has recently been built at Philadelphia for the Mexican and Southern Pacific railroad. The engine weighs within a fraction of 60 tons, has 8 driving wheels, and a pony (two-wheel) truck. The weight is so great that the Western railroads, over which it must pass, will not permit it to go over bridges, so it will be taken to pieces and carried over in sections. It passed over all the bridges of the Pennsylvania road without being dismantled.

EDISON'S MECHANICAL DEVICE.—One of the most interesting and useful of the mechanical devices which Mr. Edison employs in his electric light apparatus is his plan to prevent the wire fusing, and this it is claimed, has been accomplished by so applying a small bar that it will expand the instant the wire reaches the fusing point and intercept the flow of the current through the wire sufficiently to prevent fusion.

SCIENTIFIC PROGRESS.

Bioplasm.

Among the recent discoveries in science, none perhaps will prove of more utility to man than those relating to bioplasm, because they throw light on physiological questions, particularly those concerning the construction and nutrition of the body and the causes of disease. It was formerly supposed that our bodies were alive from top to toe, inside and out; but this is found to be a mistake. Only about one-fifth part is alive; the rest is formed material. Everybody knows that a tree may become so hollow that only a shell is left; yet the tree may grow and mature buds and leaves and fruit. It is because the outside of the tree—the bark—is alive; the wood is non-living; it is simply formed material. Now the body is not like the tree—alive only on the outside; but the living portion and the formed material exist together in every part—in every tissue, organ and vessel.

A slight abrasion of the cuticle, or the rupture of a cell, is followed by particles of fluid which were formerly overlooked as of no account. But the microscope has revealed to us that this apparently useless, insignificant ooze is the vital, living part of the body; it is *bioplasm*.

This is the mechanic, the skilled artist, that constructs the cells, builds the organs, and perhaps, under the direction of a higher power, adapts each part to one harmonious whole.

For the last 15 years, certain English and German physiologists have spent much time with the microscope, watching this little workman. They have seen it forming tissue, muscle and nerve, changing food into blood, making the secretions; and, as parts of the body became worn and effete, silently disintegrating and utilizing them, or removing the useless parts from the body.

The first decided knowledge of bioplasm came by accident (if finding a thing we are searching for can be called accident; is it not rather revelation?), by ascertaining that when a piece of live tissue is immersed in a solution of carmine the bioplasm is stained, and the formed material is not stained. This discovery has enabled observers to find and watch this little workman, while busy in constructing every part of the body.

Bioplasm is the builder not only of the body, but of all animals and plants. To it every organized form, whether animal or vegetable, owes its formation and growth.

Bioplasm is a clear, colorless fluid, like thin mucus. Only microscopes of the highest power are of use in studying the substance; for the largest normal masses are not one-thousandth of an inch in diameter; but such microscopes fail to detect in it the least sign of organization. Yet this apparently unorganized substance is the cause of all organization. It is a medium through which dead inorganic matter becomes living, organized.—*Journal of Chemistry.*

POSSIBLE EFFECT OF THE MOON IN EARLY GEOLOGIC TIME.—In a note to *Nature*, Mr. W. Davies writes: "In considering the climatic changes which have evidently taken place on various parts of the earth's surface, it seems to me that what may have been a very important factor has been rather strangely left out of calculation by physicists, never having been noticed hitherto, as far as I am aware. It is that of the heat which must at one period or the other have been transmitted from the moon. There can be scarcely a doubt that this must at one time have influenced the earth's climate to a very powerful degree, producing the effect of a second or additional sun. In the absence of any perceptible marks of atmospheric or aqueous erosive action on the moon, it is at present impossible to arrive at an idea of its relative age, or at what period its heat may have been most abundantly radiated; but if the much hotter climate which once prevailed in northern latitudes could be referred to this cause, it might give us some clue to the difficulty. Something also might be done in comparing the various changes of climate which have taken place in certain parts of the earth's surface, as indicated by geological evidence, with the actual course of the moon. The subject is at least worth entertaining, and may be recommended to the consideration of physicists."

SAFE AND CONVENIENT METHOD OF TESTING DYNAMITE.—The *Chemiker Zeitung* contains a description of a method of testing dynamite. The percentage of nitro-glycerine is determined by extracting it with ether, which dissolves it, but leaves the infusorial earth unchanged. The difference in weight of the dynamite and of the infusorial residue, directly yields the percentage of nitro-glycerine. In order to ascertain whether the dynamite contains any other bodies soluble in ether, the ether extract is diluted with water, which precipitates any foreign substances present.

A NEW BLASTING AGENT.—In Stockholm the following recipe has been given for a new blasting agent: In wooden or gutta-percha vessels 5 to 20 parts sugar or molasses are ground with 25 to 30 parts nitric acid, and 50 to 75 parts sulphuric acid. Of this mixture 25 to 50 parts are mixed with 15 to 35 parts nitrate of potassium and 15 to 35 parts cellulose. The agent is called nitrolin.

Occlusion of Hydrogen by the Metals.

In his notes of interesting things seen at the Paris exposition, Professor B. Silliman writes to the *Engineering and Mining Journal* of the occlusion of hydrogen by palladium: "The late Dr. Graham, of London, the distinguished chemist and Master of the Mint, first described what he called *occlusion* of hydrogen in the pores of the most solid fused and coined palladium, a property in virtue of which palladium can imbibe, so to speak, more than a thousand times its own volume of hydrogen gas and hold it with great permanence at ordinary temperatures. This is not a fact of merely curious scientific interest; nor is it peculiar exclusively to palladium; for Dr. Graham found that some meteoric irons, especially that of Lenarto, which he specially studied, held also many occluded volumes of hydrogen gas which had accompanied the meteor from the realms of space. Considering the enormous condensation of hydrogen occluded in palladium, Dr. Graham was led to the not improbable suggestion that this element, which others before him had suggested might be a metal in vapor, must exist in palladium *as an alloy*, and he was thus led to propose for the metal the name "Hydrogenium." This class of facts had quite recently received great expansion by the researches of Dr. Wright, of Yale, who has followed the subject into the domain of astronomy, and drawn important inference respecting the tails of comets and nebulæ as connected with the occlusion, not only of hydrogen, but other gases in meteoric stones and irons.

Increased Weight and Volume of Metal by such Occlusion.

This curious subject, so full of scientific interest and fertile of speculation, has a magnificent illustration in the present exhibit of Messrs. Johnson, Mathey & Co., who show a disc of palladium within which one thousand volumes of hydrogen gas are condensed by occlusion, a volume of gas which would be represented by a column of 2,000 millimeters in hight and 100 millimeters in diameter. The original palladium disc had exactly 100 millimeters diameter, and a thickness of precisely two millimeters. It was, before imbibing the enormous volume of hydrogen which it now holds, perfectly flat; and it was gauged by a ring within which it exactly fell. Now the disc is a concave mirror, the new form being occasioned wholly by the molecular displacement due to the hydrogen it has absorbed; it no longer enters its gauge ring, for its 100 millimeters diameter are now enlarged to 102·5 millimeters, and its original weight of 187·3775 if now increased to 188·2882 grams. This remarkable absorption of hydrogen has no visible effect upon the luster, color, or tenacity of the palladium-alloy of hydrogen, if indeed it be an alloy. The hydrogen absorbed by palladium enters this metal, when it is made part of the circuit of a voltaic battery the gas usually evolved at the positive pole being then taken into the substance of the solid metal."

UNIFORM TIME FOR GERMANY.—The question of establishing one uniform time for the whole German empire is being just now much discussed in various circles in Germany. Many persons regard the existing condition of things as very inconvenient, especially in connection with telegraphic communication. Metz, in the extreme west, is about an hour and seven minutes later than the extreme eastern frontiers. Opinions are agreed that taking into account the geographical position of Berlin, which is not very far from the central meridian of the whole country, the metropolitan time will be the most suitable for selection as the normal time for the entire empire. This will involve the least departure from astronomical exactness which is compatible with general uniformity. The difference between Berlin and the eastern frontier is little more than thirty-seven minutes; between it and Metz is less than thirty minutes. It is understood that the matter has already engaged the attention of the several federal governments, and that it will be most carefully considered in all its bearings before a decision is arrived at.

"DENDRITIC" SPOTS ON BOOKS.—Few persons familiar with old books have failed to observe dark specks here and there upon, or rather within, the substance of the paper, which, upon close examination, especially with a lens, are seen to have the same dendritic appearance that we find in moss-agates, and upon the naturally-fractured surface of other compact rocks. It is well known that such markings on the stone, are generally produced by an oxide of manganese; and the similar markings upon the paper are doubtless due to the same cause. The following is suggested as an explanation: Binoxide of manganese is sometimes used in some of the processes of bleaching the pulp. Minute portions of the mineral would naturally remain in the manufactured paper, which by a slow reaction would be restored to an oxide again, in the process of which it would assume its characteristic dendritic form.

DELICATE REAGENT FOR COPPER.—Dilute solutions of copper salts, it is well-known, give a deep blue with ammonia. F. Weil, of Paris, announces a still more delicate test for copper, namely, to add to any copper solution double its volume of pure hydrochloric acid, which produces, especially on boiling, a yellowish-green color, even when the quantity is too small to be weighed.

Mining Share Market.

The market during the past week has run pretty even, with some improvement shown in the shares of leading Comstock mines. This improvement has not been due to any actual developments made meantime, but to a growing belief, or rather hope that such would soon occur at some point along the line of the deep explorations now in progress there. There seems also to be a growing conviction in the public mind, that these mines are likely to be administered with more economy hereafter, than has in times past characterized their management. That the burdens heretofore imposed upon this class of shareholders will be somewhat lightened, for a time at least, may reasonably be hoped for, as most of the prominent companies have now got their working and prospecting shafts sunk to great depths, have these shafts well outfitted with powerful hoisting and pumping machinery, some of them being also supplied with extensive reduction works, their current expenses ought not to be very heavy for some time to come. Besides these costly equipments, much dead work has been done, further diminishing necessary preliminary expenditures in the future. The Comstock mines have now been put in easy communication with the outside world, and with the fuel and lumber supplying woodlands, as well also as with many of the larger reduction works, through the construction of railroads, securing to them great advantages. Then it may be expected that some gains will accrue to the various companies prosecuting deep explorations through the completion of the Sutro tunnel, now sufficiently advanced to be of service to a portion of them. During the week a couple of the so-called "bucket shops" operating in this city, which had before been partially strangled, have been effectually choked to death. If there are any more of these swindling concerns left, it is to be hoped that they will in like manner undergo speedy strangulation. As our mining shares are being extensively listed on the New York Stock Boards, there seems a probability that they will meet with considerable sales in the East, provided that these offerings embrace only stocks of solid merit. It will be to the interest of companies intending to avail themselves of this new opening for the sale of their shares, that it be not deluged with the stocks of "wildcat" concerns, of which we have such a super-abundance on this coast.

The Fire-Boat.

Messrs. Dickson, De Wolf & Co. have sent the following handsome compliment to the Harbor Commissioners, touching the powerful fire-boat *Governor Irwin*.

To the Honorable, the Board of Harbor Commissioners, San Francisco—GENTLEMEN: In the name of the owners of the ship *River Nith*, we have to give you our sincere thanks for your great politeness and promptitude in tendering us the use of the fire-boat *Governor Irwin*, on Saturday last, when the cargo of the *River Nith* was discovered to be on fire. The efficiency of the *Governor Irwin* in extinguishing fires is undoubted, and the quiet, unostentatious and active exertions of the Captain and his crew beyond praise. Though in business here for a number of years, it has been very seldom that we have had the pleasure to be so thoroughly satisfied with any occurrence as that in the assistance rendered to us by yourselves and the *Governor Irwin*. We have the pleasure to remain, gentlemen, your most obedient servants,

DICKSON, DE WOLF & CO.

The fire-boat alluded to, we described in detail a short time since. She has two of the well-known type of Hooker patent steam pumps, manufactured by W. T. Garratt. These pumps have 15½-inch steam cylinders, 9-inch water cylinders, and 24-inch stroke. When at work they throw a deluge of water, about equal to what would be thrown by eight of the best steam fire-engines. The fire-boat has been a great success, its efficiency being universally recognized wherever it has been used.

Bullion Shipments.

Since our last issue shipments of bullion have been as follows: Standard, Jan. 14th, $14,579.40; Northern Belle, Jan. 13th, $3,184.40; Alexander, Jan. 18th, $6,000; Tyho Con., Jan. 13th, $7,914.78; Grand Prize, Jan. 20th, $23,000; California, Jan. 18th, $94,259.02; Bodie, Jan. 17th, $17,000; Northern Belle, Jan. 15th, $2,574.52; Hillside, Jan. 20th, $5,950; Christy, Jan. 20th, $6,481; Con. Virginia, Jan. 18th, $29,288.42; Tybo Con., Jan. 14th, $4,045.16; Standard, Jan. 18th, $15,561.58; Ophir, Jan. 18th, $20,789.19; Tybo Con., Jan. 17th, $4,064.60; Argenta, Jan. 19th, $5,847.38.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

THE MONTERICHARD.—*Dispatch*, Jan. 18: The sinking of the last one hundred feet in the Monterichard mine will probably be completed this evening—making the mine now about 360 feet in depth. Some of the rock from the bottom of this shaft has been brought into our office, which, indeed, has a very flattering look. It appears to be of a much better quality than that taken from nearer the surface, besides being very rich with black sulphurets, which has heretofore been very scarce in the developed portion of the mine. The lead continues its width of from two to three feet, with no indication of narrowing. The miners think the rock will average a yield of $25 per ton.

THE rumor of the caving of the Pennsylvania mine, to which we referred last week, proves to have been well founded. The poorly-timbered shaft gave way, the mill was rendered useless and about fifty square feet of the surface caved in. It is wonderful that no lives were lost. A new shaft will have to be sunk and the mill have to be moved. Next time it is to be hoped that the work will be done with a view to security and not for cheapness.

THE old Drytown, or Seaton, as it is better known, has been started up again by the owners of the Little Amador company, under the superintendency of Mr. R. Johns. They are at present engaged in cleaning out the old tunnel. It is said they intend putting up new hoisting works some time next spring.

THE Centennial company are still running their mill of 20 stamps. It is rumored that the company have declared an assessment of ten cents per share.

THE mill for the Moore mine is nearing completion, and will probably be ready for operation by the time the necessary piping, etc., are completed for the conduction of water. A large quantity of splendid rock is now on the dump awaiting the readiness of the mill.

BUTTE.

AN OLD MINE RE-OPENED.—*Mercury*, Jan. 17: Work was resumed Monday upon the old Banner mine, located across the river, four miles from the city, at the foot of Table mountain. At one time, in the days of old, when this was one of the most prosperous mining districts on the coast, the Banner mine was a bonanza, and was believed to be the richest mine in the State. In 1860, a cave occurred on the claim and work was discontinued. Since that time it has lain idle. Prior to this mishap, the proprietors, Messrs. J. McSmith and E. M. Sparks, had made fortunes out of the property and therefore neglected to repair the damage done by the disaster and continue operations. Recently San Francisco operators and capitalists have been negotiating for an interest in the mine, which they have now secured, and one of the principal owners, Mr. Kinney, informs us that the company intend to push the work and develop the resources of the claim to their fullest extent. The intention is to sink a shaft through the *debris* until the old workings are reached and then resume operations where the former operations ceased. Mr. McSmith retains an interest and will act as Superintendent of the work. A quartz mill will be erected as soon as necessary, and judging from the past record of the lode, there can be no doubt but what the company will reap a rich harvest.

CALAVERAS.

INCEPTION OF A GREAT ENTERPRISE.—*Chronicle*, Jan. 18: Next Monday morning work will be commenced, by the Happy Valley Blue Gravel and Hydraulic M. Co., in prosecution of the great enterprise to which references have previously been made in this paper. To refresh the recollections of our readers, however, we will repeat that the company was formed for the purpose of working the well known Sport Hill and Happy Valley hydraulic mines, embracing a large scope of rich gravel. The principal obstacle now in the way of profitably working the ground is the want of "dump" and the attention of the company will be first directed to supplying that deficiency. With that object in view a tunnel is to be run from the slope extending down to the Calaveras river through to the mining ground designed to be worked—starting at a point low enough to drain the deepest part of the "diggings" and to give the flume an abundance of "fall." The survey of the tunnel is just completed. The great bore will be 3,262 feet in length, five feet wide on the bottom and seven feet high. We understand that contracts have already been let and that ground will be broke next Monday morning. It is an undertaking of magnitude, but it is the opinion of miners generally that the enterprise will eventually prove a profitable one.

GWIN MINE.—Everything continues to progress favorably at the Gwin mine. All the stamps are kept in constant operation, the batteries being fed, principally, from the 1400-foot stopes. The ore mined is not especially high grade, but the quality of the rock is sufficiently good to permit of the declaration of handsome dividends monthly. The 1500 level is still being extended north and very fair ore is being taken from the higher stopes. The Gwin mine has been a steadily paying property for years, and while there is no probability that it will ever discontinue its golden favors, the indications are favorable to an enchanced yield in the near future.

EL DORADO.

THE MINES.—*Mountain Democrat*, Jan. 18: The new pumps are at work in the Springfield mine. The shipments are the same as usual, and the rock looking well. The McNulty mine has been thoroughly prospected, and the Superintendent is confident of success. Accordingly a mill and hoisting works are in course of erection at the mine. The German mine, near the McNulty, is being worked by a company from San Francisco, and is paying well. The rock taken from the Central mine, near the Springfield, promises to pay well, and will be thoroughly tested by the company in charge. The Pocohontas mill made a four days' run on rock from the Condo & Williams mine, and cleaned up $4,000. Work has been discontinued for a time in the Pocohontas mine, but the mill is kept running on rock from different mines. It has made quite a lively little burg of Logtown.

INYO.

KEARSARGE.—*Independent*, Jan. 18: The work of deep mining on the south side of Kearsarge hill, by means of a deep base tunnel, has been settled upon by the Kearsarge company, and the enterprise begun by laying in timbers and commencing the preliminary grading. The tunnel, as reported to us, is to be wide enough for a double track and will start into the mountain immediately above the mill. It will be from 1,500 to 2,000 feet in length, cutting known stratas and ledges from 400 to 1,100 feet in depth. The concern is backed up by fresh capital and the work in hand is to be speeded by all modern methods of power drills, etc.

THE MODOCK.—Work on the tunnel is progressing here as usual, though the power drill has got into soft ground, in which it does not make quite as rapid progress as in harder rock, where the concussion of the drill would more perfectly clear the hole of dust. Nevertheless, fair progress in the tunnel is being made, and never at such comparatively small cost in all departments as here of late—a result due in good part to an improved system generally, as well as in the use of improved machinery, particularly the drill, which is a great institution itself. Week before last the total length of tunnel was 830 feet, and each week adds from 43 to 50 feet to its length. This tunnel constitutes the 1000 level, and in about 250 further, will reach the vertical line and point of connection with the shaft. At the time mentioned the shaft was down a little over 900 feet. Within four or five weeks, according to indications in both tunnel and shaft, especially the former, we may look for important developments in the Modock.

MONO.

BODIE DISTRICT.—Bodie *Standard*, Jan. 18: The work of development has advanced steadily and favorably the past week. The late rich strike in the Standard mine is turning out all that was expected. A good ore find has been made in the Tioga. In the Syndicate, Blackhawk, Dudley, Red Cloud, Noonday and Goodshaw the prospect improves daily.

BODIE.—The new shaft is now down 349 feet, which is 42 feet below the second station. The second level is being advanced rapidly, and connection will be made with the old works in a short time. The south drift is in 350 feet. The ledge in the face is looking well. The drifts north and south at the bottom of the Bruce winze are each being advanced, and the ledge is as large as ever in both directions. Ore of a very rich quality is being taken from these drifts. The usual quantity of ore is being shipped to the Syndicate mill, and it is probable that the shipment of bullion this month will considerably exceed that of last month.

AURORA TUNNEL.—The shaft on the Silas B. Smith ground is down 170 feet. The last 30 feet has been in an entire change of ground, having passed through the blue rock characteristic of the west side of Silver hill. The bottom is now in a most favorable vein formation, being full of seams of quartz. The Smith location is the oldest on Silver hill; and the course of the rich ledges in the Bodie mine indicates that they pass through this ground, and it is believed that the south extension of the rich veins mentioned, as yet undiscovered, will be found in the Silas B. Smith. Crosscutting will be commenced at a depth of 200 feet.

BULWER.—There has been no change worthy of note in the mine during the past week. The ledge in the south drift is 18 inches wide, and looks very well. The ledge in the upraise is two feet wide, and the ore at this point is very rich. The Stonewall ledge is looking as well as usual. There are now at the Bodie mill 700 tons of ore.

GOODSHAW.—The shaft is now down 410 feet. The formation in the bottom is porphyry mixed with stringers of quartz, and the indications are considered favorable. At a depth of 500 feet crosscutting will be commenced. The machinery works well.

MONO.—In consequence of the great increase in the flow of water, it has been very difficult to work in the bottom of the shaft. The station timbers at 400 feet have been put in, and one set below. Will commence opening the station immediately.

BODIE TUNNEL.—The tunnel is now in over 700 feet. The face of the tunnel is still in a favorable formation, and ventilation continues good.

NEVADA.

MILTON M. CO.—*Transcript*, Jan. 19: We are in receipt of the annual report of the Milton M. & W. Co., for the year ending Oct. 31st, 1878. The net receipts were as follows:

French Corral mine	$225,231
Manzanita mine	81,730
Water sales	51,085
Rebate on powder	2,500
Sales 322 shares of capital stock	32,200
Miscellaneous	6,484
Total net receipts	$399,230

Nine dividends were paid during the year, amounting to $21.50 per share, the same aggregating $270,748. The remainder of the proceeds was applied to the reduction of the outstanding indebtedness, construction, etc. In December, 1877, the debt due on demand was $350,000. Of that amount, $300,000 was funded on the 1st of January, 1878, in 300 bonds of $1,000 each, bearing 9% interest, of which 50 are to be taken up each year, commencing January 1st, 1880. The gross yield of the French Corral mine for the past fiscal year was $363,976, and of the Manzanita mine $173,784, both amounts representing gold. Nothing has been done at the mines since October, 1878, for want of water.

PLEASANT VALLEY MINES.—The Badger Flat Hydraulic M. Co., near Novey's ranch, have had five men at work fitting up for the rains, and are now all ready. Free water from the ravine is used, it being conveyed by 2,000 feet of 11-inch pipe, and having 136 feet fall. The claim has been worked by the present owners for three years past, last year working off a piece of ground 128x12 feet, which cleaned up $4,000. The bank is about 20 feet high, and the pay dirt is from five to six feet deep. As soon as water can be obtained the mine will be started with full force. The Nigger Creek hydraulic mine, which has been worked the past four or five years by the same owners, giving employment to a number of men, is in good shape for the rainy season. It is located about one mile south of the Hudson mine, and has a supply of free water to rely on. The pipe is 11-inch, and something like 300 feet long. The fall is nearly 75 feet. There is a small hank, but the pay streak is thought to be deeper than the Badger Flat Co's. Nine thousand dollars is reported to have been taken out here last year.

THE HUDSON MINE.—Supt. Skiff Murchie was in town yesterday. He says the snow is rapidly disappearing from the locality of the Hudson mine. Everything is working smoothly at the mine, with the exception that the water in the ditches freezes up and the mill can only be run half of the time. The ledge continues its usual favorable showing. The Boston Co. have just got through cleaning up. The result is reported to be very satisfactory. There is no water in any of the ditches, the frost and snow shutting off all the supply.

MINES SHUTTING DOWN.—The continued cold weather is having the tendency to interrupt operations at some of the largest quartz mines in this district. The main trouble experienced is from the freezing up of water ditches connected with the batteries. At the Murchie more or less delay has been met with from this cause. The Wyoming shut down last week. Thursday the Providence and Merrifield followed suit. A large number of men are thus temporarily thrown out of employment.

PLACER.

COLLINS' HILL QUARTZ LEAD.—*Herald*, Jan. 18: During the last of 1878, a party of 21 men from Portland, Maine, came to California. They brought with them an invention for saving fine gold from either sand or gravel. Five gentlemen of the company are now stopping in Auburn, while other members have gone to other parts of the State. They are stalwart and practical men, of precisely the kind and class who are needed to help the unbounded resources of the Golden State. There is room everywhere for such men. Immediately on their arrival here, the five new-comers commenced to prospect; and, it gives us pleasure to record the fact that they have uncovered a quartz ledge on Collins' hill, above the slaughter house, outside the boundary of Mr. Collins' ranch, over which the people of Auburn have tramped for the last 20 years. On Tuesday last the company pulverized a few pounds of their quartz in a hand mortar, and they obtained a splendid prospect. They are now vigorously at work, going down on their ledge.

OPHIR ITEMS.—The St. Patrick mill will be again running on the 25th, when the whole gang of 24 men recently discharged will again be put to work. Extra hands are already being put to work in the shaft. Mr. Shurtleff, of the Duncan Hill mine, has 50 tons of rock at Pugh's mill ready for crushing, which is expected to yield good pay. The extension of the old Crater mine is about to be re-opened. A good deal of prospecting is going on among the old claims, and if sufficient water he had, Ophir will soon be one of the liveliest mining camps in the county.

SHASTA.

COPPER CITY.—*Independent*, Jan. 16: W. B. Crane made a test at smelting some copper ore last Wednesday, and the result was very satisfactory; and Mr. Crane will soon be turning out copper in large quantities, as the new smelter when completed will be of 20 tons capacity per day. Superintendent Charles Dunn is pushing work as fast as possible, with a good crew both day and night, in his new tunnel on the Northern Light. The bullion shipped from the Extra Co.'s mill the past week, has been much higher in gold than the average of the bullion heretofore shipped, two of the bricks containing about $1,200 each; and being pro-

Mines and Works of Almaden.—No. 19.

FOURTH PART.

Administration and History of the Mines and Works.

Translated for the PRESS from "ANNALES DES MINES."

II. History.

The Arahic etymology of the word Almaden (the mine) would give reason for the belief that the discovery of the mines of mercury in that region was not anterior to the conquest of Spain by the Moors. But tradition attrihutes to them a much more remote origin, aud puts hack the time of their first exploitation as far as the Phœnicians. It is at any rate ecrtain that the Romans knew of them. Theophrastes (522 B. C.,) affirms that they employed and held in high esteem the firm and fine grained cinnabar which came from Spain; and Pliny recouuts that this cinnahar came from the country called Sizaponensis. Other historians, naturalists and geographers state that of all the mines of ciunabar known to the ancients the most famous was that of the country of Sizaponensis—(Almaden). It was appreciated to the highest degree for the purity of its cinnabar, which made it unique from this point of view in all the Roman empire. It is known that they transported cinnahar from Almaden to Rome under the name of *stone-metal*, in chests (well made), and that each voyage they carried away 10,000 pounds.

They ignore, indeed, the exact use to which the ore was put; and there is every reason to believe that the applications were less numerous than they are to-day. It is certain, however, that they purified it, by a sort of mechauical preparation, no douht, and tbat it was at times used by painters, and hy the Roman ladies for the same purpose. Pliny says, however, that they hurned it and washed it, whicb seems to indicate that they extracted the mercury from it.

The hahit of adulterating it with minium from Spain (from Carthageuia and from Linares, probably) shows tbat from this period it was an article of merchandise of high value.

The word Sizaphoue, generally employed in the ancient chronicles to designate the region where Almaden is found to-day, leaves not a douht whence the Romans obtained their cinnahar. They have also discovered in the old works numerous antique remains, and particularly a great numher of Roman coins.

But the exploitation of the mines of Almaden did not hegin to be developed until the discovery of America had opened to their product a large tield for the treatment of silver ores. Previous to this the mines of Almaden, following the vicissitudes of the country in which they were, changed their proprietorship several times, either owing to conquests or as the consequence of royal gifts. Thus, in 1161, king Alphonse VIII. granted to Count Nuno, and the Chevaliers of Calatrava, the towns and the mines of Chillon and of Almaden. In the 14th century the mines paid a tithe to the Archbishop of Toledo. From 1499 to 1512 it was again the royal treasury which exploited them ou its own account.

The annual production at this epoch was not more than 23,000 kilograms of mercury. Then the treasury, emharrassed hy several dehts which it had contracted to the German hankers Fugger, decided to ahandon to them, in 1525, the ownership of Santiago, Calatrava, Alcantara and the pasturage and mines of Almaden, for three years. But at the expiration of this term, the contract was renewed and the mines remained in the hands of the Fuggers or Fucares until 1563. At this last date they had entire charge of the exploitation, for which they furnished to the treasury annually a quantity of mercury which varied from 46 to 200 tons. The situation remained the same until 1624.

It is not known exactly what was the product of the mines during the first 38 years (1525–1563) of the administration of the Fuggers; in the 61 other years (1562–1624) the average annual product was 140 tons of mercury.

In 1625 the Fugger contract was prolonged for 20 years, with the ohligation of furnishing each year to the treasury at Saville 184 tons of mercury and 6,900 kilograms of vermilion.

In 1646 the treasury resumed the exploitation on its own account (Real Hacienda), with an administrator who had the same jurisdiction as the Counts Fugger, who was placed under the direction of the Council of Finance.

Later, from October, 1708, to January, 1717, it was under a special council *la Junta de Azogues;* then from 1717 to 1735 the council or *Junta de India*. In 1735, hy decree of Don Jose Coruego y Ybarra, there was established a trihunal called "General superintendence of mercury," to which was given the decision of all questions relative to the mines of Almaden.

The "superintendence" retained these prerogatives during more than a century, till 1845; it then lost these general and judiciary powers, and only retained the administrative, which the superintendeut still exercises at the present day.

The collection of documents helonging to the mines of Almaden gives some details of the exploitation of the mines of Almaden sinoe the end of tho 15th century.

In the manner of the Romans, who, in Spain, generally employed a series of vertical cuts or shafts, at small distances from each other; during this period numerous excavations were made which were known under the names, San Sebastian, Mineta Alta, Mineta Baja, Furriaga, Contramina, Antigua, Mina Del Pozo, etc., rather hadly arranged and seeming to he placed in the vicinity of the shaft at preseut existing, the San Aquilino.

The old mine of Pozo, ahandoned hetween 1590 and 1615, had arrived, they said, at a depth of 209 meters; at this level it finished hy heing no longer exploitable, on account of the increase of the expense, and of the difficulties of drainage and of supporting. It is even helieved that the works attained, in certain points, a depth of 250 meters, and a length of 500 meters.

On leaving the old mine, they directed themselves towards the actual mine of Pozo (they call hy this name the western part of the veins of Almaden and particularly the veins of San Pedro y San Diego.)

In Septemher, 1697, they discovered specimens of cinnahar in a house near *Castillo del Retamar*, at the upper part of the town of Almaden; in the same year a shaft called the San Antonio, was opened here, and massive ore was found there, toward the end of 1698. This part has received the name of *mine del Castillo*.

They commenced in 1703, the crosscuts of the first level, called *socavon del Castillo;* at 207 meters from its heginning, they came across the shaft San Antonio, in 1706.

At this period they employed slaves for draining the mine hy hand; the supporting was all accomplished hy timhering. In 1755 a fire took place in the mine, the wood hurned during 30 months; this caused great trouhle, and gave rise to numerous accidents; finally the mine was flooded, and its future seriously compromised. Some engineers were then called from Germany, who succeeded in getting things nearly into condition again towards 1760. In 1791, the steam eugine of Watt, of which we have previously spoken, was estahlished for drainage, and this in 1873, was still the only steam engine at Almaden.

Towards 1800, the engiueer of the mines, Don Diego Larranaga, proposed and adopted the present method of exploitation. The works at that epoch, in 1803, attained a depth of 200 meters. It is evident then, that in 73 years tbey have descended only ahout 90 meters, and certainly they have furnished a considerahle quantity of mercury, as is seen in tbe following table, with which we finish this work:

The Amounts of Mercury Furnished by the Mines of Almaden from 1564 to 1875.

Years.	Weight in tons.
1564-1625	8,083.282
1625-1645	3,680.000
1646-1651	757.364
1652-1653	190.099
1653-1655	405.402
1655-1656	54.513
1656-1665	724.988
1665-1668	330.071
1668-1672	465.124
1672-1673	188.410
1673-1677	458.254
1677-1680	255.603
1680-1682	200.807
1682-1685	123.132
1685-1689	302.554
1689-1696	587.646
1696-1700	363.381
Total from 1564 to 1700	17,863.720
Or on an average per year	130.391

Years.	Weight in tons.
1790-1709	1,995.848
1709-1726	3,689.124
1726-1729	nothing.
1729-1734	1,707.617
1736-1742	1,562.289
1742-1743	417.623
1743-1749	2,629.532
1750-1757	2,305.018
1757-1773	7,299.182
1774-1781	6,365.036
1781-1786	2,966.000
1787-1789	1,641.327
1789-1798	7,727.085
1798-1799	999.483
1799-1800	844.331
Total from 1700 to 1800	42,149.501
Or on an average per	421.495

Years.	Weight in tons.
1800-1805	3,129.953
1805-1810	2,548.825
1810-1815	1,753.275
1815-1820	3,497.708
1820-1825	3,527.247
1825-1830	4,448.900
1830-1835	5,774.697
1835-1840	4,873.580
1840-1845	4,596.480
1845-1850	4,433.981
1850-1855	3,503.031
1855-1860	3,798.371
1860-1865	4,179.269
1865-1870	5,387.322
1870-1875	5,714.640
Total from 1800 to 1875	60,106.379
Or on an average per year	802.218

The production during the three centuries has been, in resume:

From.	Tons.
1564-1700	17,867.320
1700-1800	42,149.501
1809-1875	60,166.370
Total	120,179.600

When we attempt to determine the value of this enormous quantity of mercury we find it rather difficult to estimate. The price of mercury reached 12 to 15 francs per kilogram before the discovery of the mines of California—New Almaden and others. At 12 francs per kilogram, the value oreated would he 1,440 millions of francs. At the actual average rate, ahout 6 francs, it still represents the sum of 720 millions of francs. These figures are eloquent enough to need no other commentary.

Concluded.

The Cone-bearers, or Evergreen Trees of California.—No. 1.

[Written for the RURAL PRESS by J. G. LEMMON.]

General Description.

Few orders of plants can be named which are of more importance to man, whether in reference to furnishing food or huilding materials, than this of the conifers, included in and forming the most of the great class of *Gymnospermæ*, or naked-seeded plants. In general character they are resinous-juiced trees, mostly evergreen, cone-hearing (though often greatly modified) with needle-shaped or scale-like leaves, very easily distinguished at sight, and inhahiting the cold or temperate regions of the earth. Except our yew, which may he poisonous to horses and cattle, as is its English congener, not a species of them all is either noxious or useless. The most of them are very valuable, and among them are the most beautiful trees in the world. It is beyond the scope of these papers to present even briefly the various uses and values derived from the piue, spruce, fir, cedar, cypress, and juniper families of our forests. They contribute three-fourths of the material for our houses, mines, hridges, roads, wharves, vessels, etc., and the Ahorigines, especially of the Southern hemisphere, depend largely upon their fruits for food.

Habitat or Locality.

Found almost exclusively in the cold regions of the earth, the cone-hearers form necessarily two great zones across the extreme land surface —one at the north and the other at the south. In these zones the conifers outnumher the other trees of the broad-leaved, non-resinous class (as oak, ash, etc.), ten to one. Great disparity is found between the trees of these extreme regions; those of Australia, New Zealand and South America can scarcely he recognized as relatives of the more ahundant and typical trees of Northern America, Europe and Asia. Some entire genera and one large suh-order, very numerous in the northern, are entirely absent from the southern zone, though in the southern regions there are found a great many genera and hut few species.

Again, the two continents have widely different forms, amounting often to generic distinctions, and very frequently to difference of species. All the drear northern regions of Asia and the more humid northern portions of Europe are forested with this class of plants. Immense forests of pine and spruce ahound in northern Russia and in the Scandinavian peninsula. These noble forests extend down as far as Germany and Switzerlaud, hut below this locality the evergreens are outnumhered by the broad, deciduous-leaved trees, oak, ash, becch, etc.

In the northern part of North America exist the most extensive and nohlest pine forests of the globe; heing often, as in the eastern United States, 300 to 500 miles in extent. The American conifers, though possessing many species peculiar to the region, are destitute of 25 entire genera of Asiatic and Australian species.

Here on this continent are found, also, wide distinctions in respect of character hetween the two coasts, Atlantic and Pacific; species of each coast being generally confined to each. There is one notahle genus of two monster species that inhabits exclusively this Pacific region—the coast redwood and our famous Sierra "hig tree."

The last climatic, or rather regional effects to be noticed are found hy comparison of our two mountain ranges—the Coast and the Sierra. In the lower, fog-fostered Coast Range is found the redwood; while in certain groves of the inland, lofty Sierra Nevada, tower up the grand, columnar kings of the vegetahle worlds.

Wide differences in species (termed *varieties*) are detected by comparison between trees of the two ends of these ranges. The Douglas spruce, of the Oregon coast, with its large trunk and small cones, two inches long, hecomes in San Bernardino, a poor deformed tree, with enormous cones one foot long. The red fir of the Oregon Cascade Range, with its medium cones having exserted hracts, becomes (according to Prof. Brewer and John Muir, hut not Englemann) in the high Sierra the large coned fir with concealed hracts.

Class Characters.

This great class of cone-bearers, called scientifically *Gymnospermæ*, or naked-seeded plants, *i. e.*, plants with seeds not enclosed in a pericarp, hut lying naked at the hase of the scales of a strohile or coue, is the last grand division of the phœnogamous plants, and comes next to the endogens or inside-growers, with which it shares the character of (chiefly) parallel-veined leaves.

The other class characters are resinous juice, mostly more than two cotyledons or parts to the seed, pitted cells in the wood fiher (detected only with a strong magnifier) and the ahsence of ducts. The latter fact accounts for the resistance to decay generally presented hy conifer trees; hut fir trees form a remarkahle exception, rotting as soon almost as poplar. The flowers are always imperfect and *diclinous* of both descriptions, *i. e., monœcious*, with the male and female flowers on different hranches of the same tree; or *'dioecious, i. e.*, with male flowers on one tree and female on another. The fruit is a strohile or cone (*e. g.*, the pines, spruce, etc.), sometimes reduced to a cup (*e. g.*, the yew), and even to a closed, herry-like ohject, called a *galbulus*, (*e. g.*, juniper). The leaves are mostly long and slender, as in the pines, sometimes reduced to pointed scales, as in the cypress family.

Obscurity of the Gymnospermæ.

Except the greatly modified family of orchids, no class of plants is more studied and is less understood than the *Gymnosperms*. Their mixed characters, resembling the great classes on each side of them, and the extreme modification of organs, hut more than all the few or poor specimens collected of such an unwieldy class of plants, have reudered research formidable to most scholars and mostly fruitless, except by a few specially qualified scientists, of whom mention may he made of Tournefort, Link, DeCaisne, Lindley, Endlicher, Hooker, hoth father and son, Torrey, Gray and Engelmann.

Even unscientific observers often speak of the resemhlance hetween the flat, expanded limhs of fir trees and the usual forms of the stems or fronds of ferns. This resemblance also led the master of hotanical science, Linnæus, to erroneously classify them together. Their resemblance to the palms is also very marked. Both form generally a single stem. All the leaves of the palm die and fall away as the stem arises; so the side limbs of the conifers generally hecome dwarfed or fall off as the tall, straight shaft towers heavenward. The leaves, mostly in fascicles or hundles (*e. g.*, pine, tamarack), are regarded as ahortive shoots. They are usually persistent (deciduous in tamarack), remaining on the tree from 4 to 12 years.

(To be Continued.)

THE ENGINEER.

Is the East River Bridge a Failure?

Notwithstanding an expenditure of nearly $13,500,000, says *Every Saturday*, the great East River hridge hetween Brooklyn and New York will undouhtedly be ahandoned. Mr. William H. Wehb, an engineer, states that the hridge is wholly incapacitated to facilitate either passengers or husiness traffic; that it is insecure aud cannot withstand the violent storms it will he subject to; that it will not bear the enormous weights that may be expected; and that the cost and delay in taking down and reulacing the top masts of vessels necessary to all that pass uuder the hridge, cannot be tolerated. It is rather late in the day to find this out, hut Mr. Wehb says that it is only an experimental hridge. It is the highest and longest in the world, and prohahly the only one entirely unsupported hy any form of stays. The history of suspension hridges in this country and in Europe shows their most dangerous exposure to he that to storms, producing oscillations and ruptures. In view of these ohjections Mr. Webb insists that it would he foolish, if not wicked, to spend more money on a "hridge that is not called for, cannot he made to answer the purposes for which it was profcssedly huilt, very seriously damages a large part of the commerce of the harhor, taxes the financial ahility of these two cities to their utmost, and cannot fail either to he taken down hy the mandate of the courts or demolished hy the winds."

Opinion of Another Engineer.

S. B. Driggs, the well-known engineer, says: "It appears to me an unfortunate coincidence that the persons who made the original estimates were the contractors for constructing the hridge under the municipal authorities, politicians and others who sanctioned it. The engineering skill which huilt the hridge over Niagara Falls, as well as many others, with such entire success, had in the Niagara case only to provide for a span of 750 feet, which I helieve is the largest that heretofore has ever heen attempted. In the Brooklyn hridge the span is, at least, 1,600 feet. Now, mark; the deflection of the cahles at Niagara Falls is more than douhle that, which, with the present hight of towers, it is possihle to give to the Brooklyn hridge cahles, and avoid interference with navigation even in a minor degree. To me it seems that the puhlic mind, in the first place, was greatly influenced hy the connection of eminent engineers with the scheme, men of whom it may he said that to attempt was to accomplish. But when they permit their names to he used as a cover for a fraudulent scheme, it is the duty of any and every intelligent and practical man to call attention to the extraordinary departure which has heen made from well-known mathematical rules, as in the attempt to span the East river.

"As I said hefore, the distance hetween the two supports for sustaining the hridge is a little over 1,600 feet, hy far the longest span ever yet attempted, and therefore the deflection of the cahles should be proportionate to the increased length of the span. Instead of this, in order to prevent lateral or swinging motion—as there can he no side stays—the supporting cahles have heeu drawn taut. This will accomplish to a degree what is required, hut at what cost? Simply at the extent of their vertical sustaining capacity, which is largely wasted in longitudinal tension, for the douhle purpose of allowing such an inverted arch to he constructed at a sufficient hight ahove water, and to make the supports as rigid as possihle.

The Towers will not Support the Weight.

"This leads me to remark that the periphery of an inverted arch must have the sustaining power of all that it is to support in its inverted condition. For it is well known that the principle of the arch must have its ends or ahutments secured immovably, in order that the

necessary sustaining powers be obtained; but, when the arc of the arch is so flat that the sustaining power is almost wholly thrown upon the abutments, it is almost impossible for the ends to bear the weight brought upon them through the necessary powerful leverage. Now, the question is purely mathematical, and therefore capable of demonstration, and viewed from a scientific point, it is evident that the decrease of every foot of deflection increases in corresponding ratio the force of weight that the supporting columns have to sustain; and thus the want of even 15 or 20 feet of necessary deflection represents many hundred tons of strain additional upon a cable, to increase the segment of the cradle which it should naturally have. Hence every large portion of cohesive power of the metal forming such cables is expended on what I cannot help calling impracticable tension. Thus I consider that it is quite hypothetical whether a bridge built on the principle of the Brooklyn affair would be safe, and this being so, I think it would be unwise to attempt its passage. The only way to make the best of a bad bargain is to have a center pier erected. This would be far less in the way than the present cables, and it should be built higher than the side supports. On this the cables could rest, and at the same time they would be stayed, while the weight would be so divided that no disproportionate strain would be brought upon either of them. Trains and carriages, as well as foot passengers, might then make use of it, and it might—I won't say would—prove profitable."

Determination of the Resistance Offered to Ships.

In an article contributed to the *Revista Maritima*, Signor A. Lettieri has described an apparatus for the determination of the resistance offered to ships by experiments on their models. In experiments of this nature, the elements to be determined are two—the uniform velocity and the resistance encountered at that velocity. The first of these is obtained by the measure of the space passed through in a unit of time. It is, therefore, desirable to have an apparatus which shall graphically denote this velocity by a curve, and refer it to a measure of the resistance. To effect this, Signor Lettieri has designed a vertical cylinder (the drawing shows the length to be 14 times the diameter, but neither scale nor dimensions are given), which revolves on a fixed axis. The upper part of this axis sustains a pulley, and a second pulley is fixed beneath the cylinder, with a small drum on its axis. A line attached to the drum passes over the upper pulley and sustains a scale pan, to which is fixed a pencil, the point of which presses against the cylinder. The model is attached by a line to the lower pulley, so that the descent of the weight corresponds to the movement of the model through the water, while the weight itself is a measure of the resistance. Movement is given to the vertical cylinder by means of a pair of conically-toothed wheels, one of which is attached to the cylinder itself. The motion of the latter being made thus uniform, and its velocity known, the curve traced on it by the pencil will indicate the relation between the movement of the model and that of the cylinder, and will form a regular spiral when both movements are uniform. The remainder of the paper is occupied by an algebraical investigation of the curves thus to be obtained, and by the relation between the weight placed in the scale pan and the resistance encountered by the model in its passage through the water.

An Improved Hoisting Plant.—Fr. Koepe, of the Hanover coal mine, at Bochum, Germany, is the inventor of an improved hoisting plant for mines, founded upon the happy thought of replacing the two hoisting drums with its two separate ropes by a single sheave with one wire. The circumference of this sheave, which is much cheaper than the ordinary hoisting drums, is provided with a wedge-shaped groove lined with wood or leather. The weight of the two hoisting cages above will suffice to prevent slipping. The machine may either be placed directly above the shaft or it may be put up beside it. By the arrangement cited, one-half of the length of rope is saved and any overwinding becomes impossible, because when one cage is at the pit's mouth, the second rests upon the bottom of the shaft, and any further winding would tend to make the rope in the shaft slack, which the counter-weight of the cage rapidly puts an end to. If a rope is attached to the bottoms of the two cages and run over a pulley at the bottom of the shaft, complete counterbalancing of the weight of the rope is effected.

The Maryland Ship Canal.—The Baltimore *Sun* has the following in regard to the ship canal across Maryland and Delaware: The lower routes seem more practicable, and probably the route commencing at the mouth of the Choptank is the most practicable of all. The temperature being higher, there is probably no danger from ice, and the Nanticoke river and Broadkill creek can be utilized so as to materially lessen the excavating. It is some distance down the bay, but comes out at Lewes, the most desirable point for the Delaware terminus, and its situation down the Chesapeake gives increased advantages to Norfolk, the Washington and other Potomac trade and steamers, the Patuxent, Rappahannock, etc., and offers to all those parts more direct communication with Philadelphia, New York, and the general outside world.

Useful Information.

Foreign Horseshoes.—Mr. Alfred Longsdon, of Queen Victoria street, writes to the *Times*: The exhibition in the streets of London of horses slipping and falling in all directions is pitiable indeed, and many of them must be seriously strained and otherwise injured. This can be so easily prevented that it is a mystery why it should not be done, especially in England, where all in reference to the horse is supposed to be so well understood. I have just returned from Germany, and during the last fortnight the roads there have been far worse than here, yet I have driven over them with as much safety and comfort as over a newly-graveled road. The means used are very simple, and far preferable to the English system of roughing, which always renders it dangerous to the horses in stable. In Germany the smith, when finishing the shoe, punches a hole in the two ends, and when the shoe is cold he taps in a screw thread and screws into the shoe, when on the horse's foot, a sharp pointed stud of an inch in length; and with shoes thus fitted the horse can travel securely over the worst possible road, and I have never known one slip either when riding or driving; and draft horses are shod in the same way. When the horse comes to stable the groom unscrews the pointed stud and screws in a button, so that no damage can happen to the horse and the screw holes are prevented from filling. When the horse is going out the groom simply takes out the button and screws in the pointed stud, and there is no fear of the horse coming back with broken knees or strained sinews, and the public are spared the painful sight of horses down or slipping in all directions.

The Advantage of Machine Tools.—For machine tools there should be a growing demand, in exact proportion as the competition of foreign manufactures is disagreeably experienced. These tools have enabled our workers in metals to accomplish the great things which, in steam machinery, have distinguished the present generation; they have, indeed, enabled the manufacturers in whatever line of business, to largely dispense with the tiny tool wielded by the comparatively unskilled workman. We direct attention to the sphere which is widening out before those machine firms who are adepts in devising apparatus to cheapen the manufacture of domestic metal wares. The hardware makers will be growing customers to the mechanical engineer. The former will be utterly unable, by hand-made products, to continue to compete with foreigners who use machinery. The machine-made goods will still continue to run down prices, and it may be attempted to meet the competition by a reduction in the remuneration paid for manual labor. But already there are indications that pretty much the limit of endurance by handcraftsmen has been reached. Our work people have not abandoned all opposition to machinery, but it is every year less displayed. If the manufacturer of locks and files, and nails, are now customers to steel-tool making firms, the manufacturers of cutlery and kindred goods must begin to seek the help of mechanical engineers, if they are not to be jostled out of the many markets in which they have done profitable business.—*The Engineer.*

Improved Method of Managing Steam-Boiler Fires.—When the furnace-door of a steam-boiler is opened, there should be a simultaneous partial closing of the damper to prevent sudden chilling of the boiler and flues. To accomplish this, with certainty, for every opening of the doors, Mr. William Weightman, of Powere & Weightman, has had arranged and applied a system of levers and rods, connecting the furnace-doors with the damper, so contrived that whether there be one or more doors to one furnace, or to which one damper is supplied, the act of opening any one door will invariably close the damper. Whether this application of simple and ingenious devices is new or not, every engineer will regard it as one of the good things for aiding the better management of steam-boilers.

Milk in Thunderstorms.—In Erzgebirge, in Saxony, where the cold water system is carried out in large dairies, an apparently effectual plan has been hit upon for preventing the milk "turning" suddenly in tempestuous weather. A thin iron wire chain is passed through the milk-pans, the ends of which are kept constantly in the cold water. Dr. Fleischman, of Baden, testifies to the practicability of this method, for, he observes, authorities on the subject maintain that milk is less sensitive to the electricity of the air than to the temperature that surrounds it more immediately. The fact that milk kept in enamelled or tinned vessels is less liable to turn sour in hot weather speaks well for this new theory.

An Artificial Tallow.—A patent for artificial tallow was issued in October last to Senor Miguel de la Vega, of New York. The inventor states in his patent, that 100 lbs. of the tallow is produced by mixing together 60 lbs. of castor oil, 10 lbs. of animal tallow, 10 lbs. of vegetable oil, and 20 lbs. of wheat flour. These ingredients are boiled together for about 30 minutes by steam heat. When the mixture cools it hardens, and resembles tallow. Cotton seed oil, or any other similar vegetable oil will answer the purpose equally as well as castor oil.

Compressing the Bulk of Flour.—A French chemist some few years ago conceived the idea that it would be practicable to compress flour so as to diminish the bulk and yet not injure its quality. An experiment was accordingly made. Flour subjected to a hydraulic pressure of 360 tons was reduced in volume more than 24%. On close examination it was found to possess all the qualities it had, previously to its violent treatment. It was then put into zinc boxes and sealed up. At the same time other flour manufactured from the same wheat, but not compressed, was sealed up. About three months after several, boxes containing both kinds of flour were opened and examined. The pressed was pronounced to be the best. Twelve months after this, another examination took place, and with the same result. The two kinds were kneaded into loaves and baked. The pressed flour made the best bread. In another year the boxes were opened and examined, and while the loose flour showed moldiness, the pressed was sweet, and retained all its qualities. Made into bread the same difference was observable.

Indelible Ink for Zinc Labels.—A correspondent of the London *Garden* says: "Many years ago a friend gave me a simple recipe for ink for writing on zinc, which I have constantly used since. It is 72 to 16 grains bichloride of platinum dissolved in one ounce distilled water. If kept corked a small bottle will last many years. The zinc labels must of course be cleaned before using. This is readily done by rubbing, either with fine emery paper or with very dilute oil of vitriol. Then simply write the name and allow the ink to dry. I have used labels of this description for years, and have never lost a name since adopting them. They have been found equally suitable for the house or the open air."

Good Health.

Is Fat Injurious?

Fats are very important elements of our food; still, goose oil, lard, tallow, train oil, fish oil, and such varieties of diet, are wisely eschewed by all except lumbermen, and those whose physical labor is very great, and who are almost constantly exposed to cold. While, therefore, the student and civilized worker wisely eschews the coarser forms of fat, he should not ignore it in some more refined and delicate form. He should instead use such as are most suitable to his taste and needs. The brain is a great consumer of fat, combined with phosphorus. No phosphorus—no thought, is a modern phrase, expressing the importance of phosphorus in mental action. As yet we are in the infancy of knowledge on this subject, but it may be predicted that when we know the whole truth, the phrase will be something like this: "No phosphorized fat, no thought." There is always some fat in most of our foods. The special forms best to make up any deficiency that may be in them are no doubt to be found in good butter and cream. There are, of course, instances in which they will not be tolerated, but these are exceptions. Fat is not digested in the stomach, but by the pancreatic juice in the intestines, nature having provided a special juice to form it into an emulsion so it may be absorbed. In this state every atom of fat is so small that it requires a microscope to detect it, and in this state it may easily be passed through the walls of the intestines and carried into the circulation. We need no better evidence of the need of fat than this careful provision for its digestion in the system. The symptoms which attend a non-use of fats in some form are coldness of the extremities, a tendency to indigestion, lack of nervous energy and power to think. Emaciation, diminished muscular power, and a tendency to consumption.

It may be true that many persons suffer from an inability to digest fats, and that sometimes they obstruct the liver and make much trouble. In all such cases it would be advisable to use them wisely and judiciously, but rarely to avoid them altogether, except, perhaps, in corpulence, where they are best used in great moderation. Lean people should use fats rather more freely than fat ones. The amount of fat necessary for a healthy working person is about three ounces daily. Persons with extraordinary working power require more than this. The starch in our food is to a certain extent a substitute for fat, and may be converted into it.—*"Eating for Strength."*

The Lesson of a Sneeze.—As a rule, a sneeze is the warning nature gives that some part of the body is exposed to a cooler temperature than the other parts, that the sneezer is "catching cold." Next to the warning, what is the use of a sneeze? It throws open the pores of the whole body, and induces a gentle perspiration; in a word, it throws out the cold. A child rarely sneezes more than twice. Perspiration is readily induced in a youth; an old man, on the contrary, sneezes half-a-dozen to a dozen times with a loud "catchogue." It is harder to set him perspiring. When one is sitting by an open window, and finds himself sneezing, nature tells him he is taking cold. He should get up instantly, walk about, and take a full tumbler of cold water to keep up gentle perspiration that the sneeze set in motion. If he does this, he will not be telling, an hour after, that he has a "cold in his head," or chest, or lungs. —*Eastern Gazette.*

Keep Your Nails Clean.

People differ much in their nail habits. As an observer well remarks in the *Phrenological Journal:* Some keep them long and pointed, like reminiscences of claws; others bite theirs close to the quick. Some pare and trim, and scrape and polish up to the highest point of artificial beauty; and others, carrying the doctrine of nature to the outside limit, let them grow wild; with jagged edges, broken tracts, and hangnails as the agonizing consequences.

Sometimes you see the most beautiful nails—pink, transparent, filbert-shaped, with the delicate, filmy little half-moon indicated at the base—all the conditions of beauty carried to perfection, but all rendered of no avail by dirt and slovenliness; while others are yet pleasant to look at for the care bestowed on them, their dainty perfection of cleanliness being a charm in itself.

Nothing indeed is more disgusting than dirty hands and neglected nails, as nothing gives one such a sense of freshness and care as the same members well kept. But one of the ugliest things in nails is when they are bitten, which, to judge by what one sees, is a habit having irresistible fascinations for those given over to it. It is an action, by the way, that has more than one significance. It may mean consideration, doubt, hesitancy, or it may mean anger or annoyance.

In Paris there are "manicures," who treat the hands of customers just as the chiropodist does the feet of people. It would be a profitable enterprise for some to start in America. Many persons are apparently too indolent or careless to keep their hands in a neat and proper condition.

Winter Clothing for Children.

The matter of winter clothing for children has not heretofore been a subject of much thought here on the Pacific coast; but in the midst of this exceptionally cold season the following hint may not be inappropriate: It is generally thought that a very proper article of winter clothing for children is a comforter swathed around the neck. This is a great error. The feet and wrists are the proper members to keep warm; the face and throat will harden into a healthy indifference to cold; but that muffler, exchanged for an extra pair of thick socks and knitted gloves, would preserve a boy or girl really warm and well. Bronchitis and sore throat have declined nearly 50% since the absurd use of high collars and twice round handkerchiefs went out of fashion, and if the poor would take better care of their children's feet, part of infantile mortality would disappear. It only costs a trifle to put a piece of thick felt or cork into the bottom of a boot or shoe, but the difference is often considerable between that and the doctor's bill, with perhaps the undertaker besides.

Diphtheria of late has been prevailing to an alarming extent in every county, east and west. At the last annual meeting of the American Medical Association, it was urged: 1. That, in case of diphtheria occurring in a pupil attending school, the patient should be wholly separated from other children until two or three weeks after his recovery; that those who had been specially exposed should be allowed to attend only after careful medical examination; that, where several were afflicted, the school should be closed and as many of the children as possible removed from the place. 2. That all clothing used by a diphtheritic patient should be subjected to intense heat, either of dry air or hot water. 3. That the room should be thoroughly ventilated during the patient's illness and afterwards disinfected. 4. That where the disease is prevailing as an epidemic, it would be desirable in summer to erect a large hospital tent in an airy position, whither all the patients might be at once transferred, and in winter a house might be converted into a hospital for the same purpose. 5. That we should treat diphtheria as we do scarlatina and small-pox.

Re-uniting of Pieces Separated from the Body.—Dr. Maas describes two cases in which pieces separated from the body were replaced, and had united. In both cases the nose was the portion injured, and in both the epidermis sloughed off, leaving the rete Malpighii exposed. The pieces were sewed on with fine sutures, between which strips of adhesive plaster were applied, and, over all, oiled silk or cotton batting, to prevent evaporation and maintain warmth. The two following rules are given: (1) The piece separated must be kept warmed to the temperature of the human body. (2) It must be replaced, whether with sutures or adhesive plaster, or both, directly the flow of blood ceases. The nutrition of the piece is supposed to be maintained by the speedy re-establishment of circulation through its vessels.

How to Kill a Tapeworm in an Hour.—Dr. Karl Bettelheim, of Vienna, narrates, in the *Deutsches Archiv*, a heroic method and nearly sure cure in the short space of time of three-quarters of an hour to two hours. It is this: He inserts a tube in the œsophagus, to the stomach, and pours down from 200 to 400 grammes of a very concentrated decoction of pomegranate root, having previously had his patient fast for 24 hours. The worm is stupefied, and passed, head and all, to a certainty; the patient has no sickness of the stomach, and no nauseous swallowing to do; and the drug is cheap.—*Med. and Surg. Reporter.*

The Week.

The event of the week is the timely, widespread and soaking rain, which, commencing on Wednesday evening, has, at the time we write, been falling moderately but steadily for nearly twenty-four hours; being the most penetrating, protracted, and in every way beneficial rainfall that has yet occurred at this point the present winter. Should it continue after this fashion for another twenty-four hours, it will, through the improved prospects imparted to our leading interests, do much to change the previous feeling of despondency and gloom to one of cheerfulness and hope. While we require a great deal more rain than we have had to date, to amply supply the mines with water and make certain the cereal crops throughout the State, the gains insured by the present storm may be estimated by the million, so much at a critical period may our material prosperity be made to depend upon the fall of even a single inch of rain. Truly has it been said that much that is common to the eastern side of the continent has been reversed here in California; and in nothing has this maxim found so apt verification as through the peculiar conditions of the climate. A pleasant winter day with a clear sky and the promise of long-continued fine weather, would, on the other side, enliven business and put everybody in the best of spirits. Not so here. We dread these fine winter days. The practical business man sees in them only ruin and disaster. To the farmer they mean poor crops; to the miner, light clean-ups; to the laboring man low wages; to the merchant dull sales and slow pay; to everybody, in short, stagnant business and hard times. Give us, however, a sodden earth and leaden sky, a down-pouring rain with a good prospect of its long continuance, and business of all kinds is at once inspired with new life.

The Heat of the Comstock.

In the year 1878 the Government of the United States commenced a work which it had too long neglected, and has since dropped only half completed. That is the careful examination of the Comstock lode, the largest deposit of precious metals now known in the world, and one of the most remarkable exhibitions of the phenomena which the earth hides within its bosom. The work was done by Prof. John A. Church, of Columbus, Ohio, in connection with Wheeler's survey of the Territories. Prof. Church spent five months in the field, and as a first result of his labors, the annual report of the Chief of Engineers contains a discussion of the heat which makes labor in the Comstock so severe. It is a matter of first importance to know whether this heat is likely to increase rapidly in depth, for it has already reached a point at which it is almost unendurable.

Hitherto nothing has been known of the cause to which this heat was to be attributed, and the only explanations given were those which had obtained authority in other parts of the world. They were two in number, both referring to the fact that the rock of the Comstock region was once melted and poured out in a fluid state. According to one of these theories the erupted rock has never cooled down except near the surface. Rock does not transmit heat very readily, and when a layer a thousand feet thick has become cool it acts like a blanket to keep the remainder of the mass from losing heat.

The other theory is that a mass of melted rock, or at least very hot rock exists at a comparatively moderate depth in the Comstock neighborhood, and the heat from this intensely hot center of radiation is transmitted through the rocks of the lode, keeping them warm. The rocks there were poured out at quite a recent period, and this theory merely asserts that the original sources of the melted material are still very hot and keep the crust above them at a high temperature.

Both of these theories are old and were invented to account for the fact that regions containing eruptive rocks are often found to be the seat of hot springs, and to give other evidences of heating. The springs at Steamboat merely repeat the conditions which are found at Carlsbad, Franzenshad, and other European localities, and in Mexico; and when the Comstock first came under the observation of scientific men, one of the first points settled was that the hot springs burst out from an uncooled mass of eruptive rocks, or were the last phase of the aqueous eruptions which formed the lode. Since then nothing has been added to the facts or theories, except the assertion by Mr. King that the rock is heated by the water which penetrates it, leaving the origin of the hot water still unaccounted for.

Prof. Church rejects all of these theories and brings evidence to show that the heat of the rocks is maintained by some cause that is in action now, and cannot be considered as a remnant of a fusion long passed. He calculates, for instance, that it is impossible for rock to transmit heat with such rapidity as the propylite of the Comstock does, unless it has a very much higher temperature than anything known there.

In the Yellow Jacket mine the rock at the 2200 level was found to have an average temperature of 138° Fah., and as the increase of heat in the rocks is found to be about one degree Fahrenheit for 45½ feet of depth, the temperature of the rock on the 1732 should be about 127½° Fah. Therefore between the 2200 and 1732 levels there is a layer of rock 468 feet thick, which has its under side 10½ degrees hotter than the upper surface.

Upon these facts it is possible to base trustworthy calculations concerning the source of the heat; for a third of a century ago Prof. Forbes, Director of the Calton Hill observatory, in Edinburg, Scotland, began a series of observations on the rate of heat transmission in rocks and soils. He planted thermometers in the trap rock of the hill at depths of 3, 6, 12 and 24 feet, and the readings of the instruments have been taken patiently several times a day ever since. A few years ago they were summarised by the celebrated Sir William Thomson, and it is on the results obtained by these two gentlemen that Prof. Church bases his assertion that no possible rate of heat transmission could keep up the high temperatures found in the mines.

Sir William Thomson found that a plate of trap rock one foot square and one foot thick, would transmit in 24 hours, for each degree of difference between the top and bottom of the plate, enough heat to raise 24½ pounds of water one degree in temperature. The trap of Calton hill and propylite of the Comstock are both eruptive rocks, and it is not making a violent supposition to say that they probably transmit heat with about equal facility. Therefore the stratum between the 1732 and 2200 levels of the Yellow Jacket, having a difference of 10½ degrees between the temperature of its top and bottom, should transmit enough heat in each day to raise $24\frac{1}{2} \times 10\frac{1}{2} = 255.7$ pounds of water one degree, provided the distance between the levels were only one foot. But we have seen that it is 468 feet, and it is a known law that the rate of heat transmission diminishes with the thickness of the stratum. To obtain the amount of heat which the rock between these levels of the Yellow Jacket is actually capable of transmitting, we must divide the above quantity by 468, which will give the amount of heat the 1732 level would receive, provided it were heated entirely by transmission from the 2200 level. Dividing 255.7 by 468, we obtain 0.55 pounds of water raised one degree in temperature, and the next step necessary is to ascertain how this compares with the actual state of things.

Fortunately this can be done, and the circumstances are an excellent example of the value which the pursuit of knowledge, even of the most abstract kind, will eventually have. While the labors of Prof. Forbes and Sir Wm. Thomson have made an approximate theoretical calculation possible, the intelligent interest which Capt. T. G. Taylor, formerly Superintendent of the Yellow Jacket, took in his mine, has placed within Prof. Church's hands the means of comparing these theoretical results with the amount of heat actually transmitted to the 1732 drift. Capt. Taylor began in 1875 a series of observations at several points in the mine, and though a few of the records have been accidentally destroyed, enough remains to afford a valuable source of information.

The Yellow Jacket is opened by a vertical shaft to the 1119 level, and an incline to the 1531 level. From the 1531 two parallel winzes are sunk on the lode, inclining with it. They are 413 feet apart, and connected on every lower level by the main north and south drift. The mine is downcast, and the air current passes down the vertical shaft to the 1119 level, thence down the incline to the 1531 level, through a drift to the south winze, and thence down this winze to the 2200 level, the bottom of the mine. On its way from the 1531 it sends a current through the 1732, 1935 and 2040 levels, these currents being reunited in the north winze, which is the upcast. The north winze does not reach to the surface, and no air rises today in the mine, the entire current flowing into the Imperial and Bullion mines, both north of the Yellow Jacket, and both of them exclusively upcast. This simple arrangement, and the fact that the drifts are not worked in now, and, are therefore free from the heat of candles, men and other disturbing causes, make the Jacket one of the best mines known for observations on heat.

Capt. Taylor has placed Fahrenheit thermometers of the common kind, with japanned tin cases, at the surface, foot of the vertical shaft (1119 level), 1732 south and north winzes, 1935 north winze, and 2040 south and north winzes.

Prof. Church says that the instruments, which are of ordinary construction, should be replaced by standards, and that the favorable circumstances of the mine will repay careful work upon it. According to his measurement, the mine receives about 18,000 cubic feet of air per minute, which divides into three splits in the south winze, one of which travels through the 1732, 1934 and 2040 levels respectively. The air gains in temperature in descending the south winze, and also in passing the 413 feet of drift to the north winze. On the 1732 the amount of the gain in six months was—

HEAT OBSERVATIONS, YELLOW JACKET MINE, 1732 LEVEL, 1877.

	South Winze.	North Winze.	Gain.
January.....	75.62	86.50	10.88
February.....	76.85	83.87	7.02
March.....	76.10	88.89	12.79
April.....	77.48	88.23	10.75
May.....	81.42.	91.11	9.69
June.....	79.39	91.62	12.23
Average for six months.....			10.56

Eighteen thousand cubic feet of air, divided among three drifts, would give each one 6,000 cubic feet, or close on 400 pounds of air per minute. The amount of heat absorbed is 1,128-pound-heat units in traveling 413 feet on the 1732 level. This is equivalent to burning 216 pounds of anthracite coal in that drift each day.

A more striking way of stating the facts is by saying that if hard-coal fires were kept at distances of 100 feet in the drift, each one of them would have to burn 52½ pounds of coal daily to warm the air current as much as the drift does. There is not a household fire in San Francisco which could replace one of these hypothetical fires in the drift, unless it is in one of the largest furnaces used for warming a whole house.

By combining the heating power of the drift, as found from Capt. Taylor's observations, with the transmission proved to be theoretically possible, Prof. Church shows that the heat of the drift is at least six times what it could be by mere transmission.

He also shows that the heat of the rocks cannot come from the water, for the rock of the Comstock is mostly quite dry, and the dry rock is as hot as the wet. Finally, by the mere statement that the 1732 level of the Jacket has not lost its heating power, after two years' exposure to a cooling air current, he shows that it cannot be referred to retention of the heat by which the eruptive rocks were originally melted.

He maintains that the heat is constantly produced by some agency that is now acting in the rocks, and that the agency involved must be a chemical one.

Mrs. Josefa Livermore, wife of the late Robert Livermore, one of the oldest residents of Alameda county, died Thursday, last at Livermore. Deceased was born in the Livermore valley in 1810.

The steamship *Oberon*, from New Orleans for Liverpool, is ashore near Queenstown.

New Hoisting Machinery for the Comstock.

Prescott, Scott & Co., of the Union Iron Works, in this city, have just completed, ready for shipment to the North Consolidated Virginia mine, on the Comstock, the largest direct acting hoisting machinery yet built on this coast. It was designed by and built under the supervision of Mr. Wm. H. Patton, of the bonanza mines. This machinery, which is believed to embody all the latest improvements in this class of work, was set up at the foundry this week, and we had an opportunity of examining it.

Foundations.

The foundations which are already laid for the reception of the hoist are of massive stonework 24 feet deep, 38 feet wide and 56 feet long. In this, the foundation bolts for the frames of the engines have been set. The bolts vary from 2½ to 3 inches in diameter and are 20 feet long. For the accommodation of the brake frames, hydraulic cylinders, crank plates, reels, etc., the masonry is stopped off at the proper points, while the balance is carried up level to a horizontal plane of two feet below the bottom of the engine frames, which rest on a coping of the above thickness.

The hoisting plant consists of two engines, connected together at the main pillow blocks, by a common crank shaft, with accompanying reels, clutches, brakes, wheels, indicators, rods, levers, hydraulic cylinder, overhead sheaves, etc.

The Frames.

The engine frame is of the style known as the Corliss, about 24 feet long between the front ends of the cylinder and where the frames join the pillow blocks. The engines are placed 28 feet apart. The pistons are of 28-inch diameter and have an eight-foot stroke. The cylinders are cast separate from the frames that carry the cross heads, guides, etc., but are bolted to them. These frames are bored out to a diameter of 35 inches, for the reception of the cross heads. For convenience of shipping, these frames that join the cylinders to the pillow blocks are cast in two pieces and carefully bolted together. The pillow blocks are furnished with heavy side and bottom brasses, that are fitted for the crank shaft.

The Pistons.

The pistons carry spring packing. Both heads of cylinders project into the cylinder six inches, and are made concave to suit the piston. The back heads are heavily ribbed, and have a separate outside cover bolted on and turned and polished all over. The front heads form one end of the engine frame and are bored and fitted with separate stuffing boxes turned and bolted securely. All the glands of both engine and bottom of stuffing boxes are properly bushed with brass. The piston rods are of steel, six inches in diameter and about 14 feet long. The cross heads are of wrought iron, with brass shoes to fit circular guides of frames. They are keyed to their respective piston rods and are provided each with pins for connecting rod. These latter are of wrought iron, 10 inches in diameter at the middle and 23 feet long.

The cranks are of usual form, but carry crank plates that are cast in two pieces and bolted together, after being carefully fitted to the crank. These crank plates are carefully turned off at the rim for the brake straps, that are operated by the engineer through a series of levers, rods, etc.

Valve Motion.

The admission valves of the engine are of the Cornish pattern, nine inches in diameter. The exhaust valves are of the American double-disk pattern, driven by eccentric and combination of rock shafts, levers and cams. The expansion of steam is controlled by the Cross variable cut-off, made to adjust by levers held by quadrants. The steam and exhaust chests are cast on the cylinder, the steam chest being on top at each end and connected together by a 10-inch pipe with a branch for the throttle; the valves being directly over the steam ports. The exhaust chests are on the side of the cylinders. The steam and exhaust valves are of brass. The ends of the valve lifters are supported on turned, polished columns, bolted to flanges projecting from the steam chests and the side of the cylinder.

Both steam and exhaust valves are worked from one rock shaft placed above the cylinders equi-distant from each other. This rock shaft is four and a half inches in diameter, working in bracket boxes, bolted to the tops of cylinders. Motion is given to the rock shaft by a connecting rod, from an intermediate rock shaft, working in a box bolted to a foot, cast on the engine frame near the forward end of the guides. This rock shaft is 4 inches in diameter, and 14 feet long, fitted with brass boxes.

There is a 10-inch Corliss valve on each engine for the throttle, fitted with a pass-over valve in the side of the valve chest, and fitted with shaft, lever and quadrant, all of bright work. The pistons are 12 inches deep on the periphery, and 14 inches at the centers, both outsides being convex. The cross heads are all bright. The cross-head pins are of steel 6½ inches in diameter and 9 inches long in the bearing.

Reversing and Cut-off Gear.

The two reversing links are connected direct to a pin on the arm on the inside end of the intermediate rock shaft, and are of solid wrought

iron, 18 inchee between the centers of eccentric rod pins. The links are case-bardeued and work iu a solid wrought-iron link block with steel gibs. The liuk motion is all complete with suspending links, tumbling shafts, balance levers nnd weights, double quadrante, band lever and shafts, witb connection from lever on tumbling sheft to the hand lever. Thero are four eccentrics fitted to tbe crauk shaft, two for each engine, for working the links, and connected to the same by rods, fitted witb journals, keys aud gibs, these rods being all bright finished. There aro two separate eccentrics (one for each engine), for working the cut-off gear connected to it by rods and levers, with intermediate rock shaft. Tbere is a quadrant witb lever for adjusting and boldiug the cut-off gear in place, with connections of the same description and finish as the reversing gear.

The crank shaft is of wrought-iron turned, and a little over 27 feet long, and 18 inches in diameter. The wrought-iron cranks are four feet from conter of shaft to center of crank pin, the hubs beiug 36 inches in diameter and 17 inches thick. The balance wheels are 13 feet in diametor aud 14-inch face. Tho connecting rods are 22 feet long, 6 inches diameter at necks, and 10 inchee at centers.

Tho Reels and Brakes.

There aro two reels which turn loosely upon the shaft, and nre brought into actiou by clutchee which slide upon the shaft where it is planed off octagonally for greater strength. The reels nre six feet in diemeter where the flat ropo begins to wind upon itself, end can coil at lonst 4,000 feet of rope, making 15 feet in diameter when tho rope is wound up. The brake wheels nre attecbed to the reels nnd are turned off on the rims for friction brakes. These brakes on each reel consist of two upright wrought-iron trussed vibrating arms, 19 feet long, connected together at the top by a double-adjustable rod, and prepared to receive wooden shoes 9 feet long and 12 inches thick. There are two sets of brakes for each of the reels, one for operating at each side, and one set at the bottom of tbe brake wheels.

Tbe brakes nre operated by levers conuected to hand wheels by rack and pinion, and fnrnished with ratchet and pawl for holding brakes in place. The bottom brakes consist of wrought-iron straps with ndjustable screw ends, the brake straps being covered with hard wood. There are two brakes for the engines, one on each balance wheel, consisting of wrought-iron straps, operated through a combination of levers aud rods, hy a foot pedal. The brake wheels are 15 feet in diameter and 12-inch face.

Hydraulic Clutches.

The clutches for throwing the reele into gear, fit on the octagonal part of the shaft. They nre 29 inches long nnd with a hub turned 36 inches in diameter. These clutches are operated by hydraulic power, under control of tbe brakeman. When the pressure of water is turned on to the pistou of the hydraulic cylinders, it operates through suitable connections—a bell-crank lever which throws the clutch in or out of gear. There can never be any miss about the mechanism and no effort is required to connect or disconnect the clutches.

The Indicator Gear.

The indicator gear fitted to this hoisting machiuery is of a novel form, tbis being tbe first of tho kind in nse. It was recently patented, through the MINING AND SCIENTIFIC PRESS Patent Agency, by H. C. Behr, of Virginia City. As the reels on this engine operate separately, there are two indicator drums, one for each reel. Each one consists of a metal drum, fonr feet in diameter, mounted on a vertical shaft. On this drum ie a worm or spiral band of copper, mede so as to hold upon it, by epring or screw, numbers indicating positione in the ehaft. The revolution of the drnm and helix operates two screw shafts which carry an indiceting bar and pointer, said bar and pointer moving in a plane in the direction of the axis of the drum and following the helix, so as to point out the position of the cage on the end of the rope in the shaft. With the ordinary indicator it is impossible for tbe engineer to know with accuracy the position of the cage in the shaft, as the variation is so great. In this, the helix on the drum has the nnmbers upon it which indicate the certain points in the main shaft. It is marked off in feet. As the drum is rotated hy a pinion on the reel shaft actuating the drum, the pointer on the indicator bar moves vertically and the pointer indicates exactly the number of feet of rope out. The stretch of cable whcn out at great length may be calculated for and the marks or numbere changed on the helix in accordance with the stretch. The accuracy of the device is such that the engineer can tell, to a foot, exactly the position of the cage in the shaft. These drums are four feet in diameter and six feet high. The coil or helix going around it 26 times. Each turn may be marked off in 20 numbers of five feet each for 100 or 10 numbers of 10 feet each; so a whole 2,600 feet may be marked off in five-foot sections, with considerable space between. These nnmbers may be shifted at will to account for stretch of rope. On these engines there is a epur gear, secured to a follower on the brake wheel arms, to connect with a pinion keyed to the shaft carrying the worm that drives the gear on the vertical drum shnft.

Operation of the Hoist.

The engines described are bnilt to attain a maximum piston speed of 1,000 feet per minute. Thie will require about 60 revolutions of the cranks. The speed of the cages moving in the vertical shaft will vary, accordiug to the amount of rope wound npon the reels, frem 2,000 to 4,000 feet per minute. They are under tho control of a single engineer and his brakeman, the former landing the ascending cage aud the latter the descending, continually. The engineer fixes his ettention upon the indicator tbat rogisters the progress of tho ascending cage, and at the proper instant, cuts off his steam, applies his brakes to the crank plates, and stops the cage at the mouth of the shaft. Meanwhile the brakeman is lowering the other cage, watching the indicator connected with its reel. When it approaches the station he tbrewe out his clutch, by means of hydraulic power, applies his brakes and brings his cago to a stand-still. On the return run the positions are simply reversed.

Each man has, therefore, n simple duty to perform, oue nttending to tbe hoistiug and the other to the loweriug of the cages, coutinuously. By this systematic and expeditious way of working, a maximum out-put of 1,200 tons per day can ho secured.

All this machinery weighe about 400 tons, and is the largest of the class on the coast. Most of tbe large hoisting machinery here is geared, but this is direct acting. Four boilers, 54 inchee in diemeter and 16 feet long, have been shipped to accompany the machinery, these making eight boilers in all at the shaft where tbese engines are going. Each pair has donble steam drums. In the engine all the working pins throughout the valve gear are of steel, and the connections fitted with bresses, keys and gibs. All the levers, wipers, rods, rock shafts, journals, caps, connecting rods, quadrants, reversing levers, etc., are finished bright. The quadrants and levers are fitted up with spring and brass hand catches, like locomotive quadrants. All the principal eccentrics, slides, etc., are fitted with the Lonergan oilers.

Fig. 2. Section Cut "with the Grain.

The machinery altogether is very handsome in appearance, and is substantially and carefully made, reflecting credit on both designer and builders.

E. GAUGOT, the well-known mining engineer, and one of the original members of the American Institute of Mining Engineers, sailed on the steamer *Belgic* on the 21st inst., to assume the position of general superintendent and engineer of the coal mines for the Japanese government.

A Foe to the Lumberman.

Scientific investigators are continually coming to the aid of practical workers with explanations of the evils which hedge about their work and endanger its results. These explanations we seek for publication, because often a knowledgo of the evil suggests a remedy, and where this happy result deee not follow, there is still the satisfactiou of being acquainted with the occult agency which crosses the worker's pathway toward success in his nvocation. A very interesting case of timber destruction by a fungus, which penetrates the growing tree nnd honeycombs its heart without leaving any exterior marks by which the lumberman can tell the worthlessness of the timber beneath the bark, was brought to the attention of tbe California Academy of Sciences, by Dr. H. W. Harkness. As tho case is of such wide practicel interest to lumbermen and tree growers generally, we have made engravings to show tbe way in which the fungus attacks the fiber of the tree. These engravings will be fully explained in the courso of the paper which Dr. Herkness read at the Academy of Sciences, nnd which we print herewith:

During the past few years the study of the

FIG. 1. CROSS-SECTION OF CEDAR, HONEY-COMBED BY THE FUNGUS.

fungoid diseases affecting vegetation has proved to be one of much importance, not alone owing to the scientific interest attached to the subject, bnt also to the farmer as well, whose best efforts are often thwarted by the presence of a pestilence he is powerless to control. The *Peronospora*, affecting the potato, *Puccinia* and *Erysiphe* amongst wheat, are capable of destroying the fairest fields in a single night, while the *Sphæria morbosa*, npon our fruit trees, and the *Merulius* and *Polyporus*, amongst those of our forests, are but types of a large order of parasites which are eilently at work converting many of our forest trees into their original elements. In many instances it is probable that the tree has completed its growth before it is attacked, yet the external signs are so obscure as to mislead the observer, valuable trees being lost before the appearance of disease is even suspected.

A notable example in point is to be found in the Douglass spruce of our mountains; this is well known as one of our most beautiful trees, while for many purposes the timber is of great value. The lumberman suffers, however, a great loss from a form of dry rot which attacks the living trees, the presence of which disease he is often unable to detect until after much labor has been expended in preparing the lumber for market. The disease of this tree is owing to the presence of a new species of *Dædalia*, for which I propose the name, *D. vorax*, which first finds lodgment beneath some dead limb. Following the course of the limb as it enters the heart-wood of the tree, the mycelinm begins immediately to branch upward and downward along the line of the longitudinal cells. Ramifying among these it sape the cell contents and destroys the vitality of the structure. On making a section of the tree the line of devastation may he easily traced by the minute channels filled with the decaying wood. The tree once fallen, the work of the fungus does not cease, but, on the contrary, is greatly accelerated, owing to the greater amount of moisture it imbibes when in recumbent position; and hence it is that our fallen epruces so soon disappear.

But let us pass to another, the fir trees of our Sierras, for a still further proof of the work of destruction wrought upon our living trees by fungi. In the case of the fir, the fungus (with little doubt *Polyporus revolutus*—Cooke) attaches itself to the bark of tbe tree; its mycelium soou penetrates to the cambium heneath; there it epreads over a considerable space, and begine to force its way directly tbrough tbe sapwood toward the beart. Tho treo dees not, however, readily yield to tho influence of ite foe, but commences to develop new tissue, in order to arrest the extension, or partially encyst the fungus. Layer after layer of new tissue is formed, until great bulbous expnnsions are produced upon the trunk; the perasite all the while is enting its wey like a cancer, slowly but surely, into the heart, until finally, after years of centest, the tree falls a prey to its deadly cnemy. So general is this disease amongst the firs thet, as Mr. Johu Muir asserts, few, if any, die from any other cause. Thie fuugus, like the ouo before mentioned, continues its work in the fellen trees.

In the fungus I am now to speak of there ie a marked exception, however, to this rule. I allude to the fungus which is at work upon our *Libocedrus decurrens*, a tree of great velue for timber, tho consumptiou of which is constantly incrensing as its good qualities ere becoming better kuown. In some localities, as can be shown, one-half or more of the trees are diseased, aud yet no exterual signs nppear by which the lumberman may determine the diseased tree from that which is sound. The method, too, by which the fungus invades the tree is most eingularly perplexing. If we examine a transverse section of an affected tree, we shall find numerous small openings, as shown in the larger engraving (Fig. 1), and which create the impression of being the work of some animal. Frequently 50 or 60 such openings may be seen in such a section. These openings vary from one-half to one inch in diameter. A longitudinal section of such a tree reveals the fact that these openings are not continuoue throughout the body of the tree, but are eimply elliptical cavities of from three to four inches in length. These openings are shown in the smaller engraviug (Fig. 2).

These cavities are filled with the dead wood, pervaded with threade of mycelium. The wood so affected becomes contracted in the cavity, is very friable and easily powdered between the fingers; the medullary rays end fibro-vascular bundles, together with the cell structures in general, maintaining their proper relations to each other. A singular fact must in this connection he noted, which is this, that along the line of this decayed wood, or in other words, the borders of these cavities, there seems to be no partially decaying or decayed wood. Between any two such cavities there is a considerable portion of perfectly sound wood, the mycelium in some unaccountable manner, finding its way through the living wood, leaving behind not the slightest microscopic trace of its progress. The cavities always appear in the dry heert-wood, and, though I have diligently sought for them, I have never yet seen one in the sap-wood.

Under treatment with suiteble reagents, the affected wood shows abundent branching threeds of mycelium traversing the entire mass. Along with these are found a considereble number of zoospores. Thus far I have been wholly nnable to detect the presence of any germspores. There is ahundant evidence, in my judgment, however, that these spores must he sought for among the roots of the tree. Yet their discovery will depend, in a great measure, upon accident, es the germ may have developed, fruited and diseppeered a century before its mycelium had finished its work. There ie ae yet no apparent law governing the distribution of this fungus among the trees of this genus. As I em informed by Messrs. Towlee & Co., who have hed large experience with the tree, it attacks equelly well those trees which grow either in moist or in dry soil. Another striking peculiarity of this fungus, and one wherein it is an exception to those previously mentioned, is to be fonnd in the fact tbat when the tree diee its ravages cease entirely.

In the cases of fungi destroying the Douglass spruce and the fir tree of the Sierras, before mentioned, we have seen the fungus continuing its work after the deeth of the tree, and becoming the most active agent in completing its destruction. In this instance, however, if the wood is not so far honeycombed es to crush under weight, it mekes a durable railway tie. Again, if snfficiently sound to hold a neil, it is as durable as any kind of timber for the purpose of fence posts. Once fellen to earth, the gients of the forest bid defiance to every form of parasitic growth.

THE impression abroad that the damage done by the storm of December 31st to the Santa Barbara wharf, materially interferes with the loading of vessels, is erroneous. But little inconvenience to the Captain, end none to passengers is experienced, as ships can come right up to the wharf inside of the break.

THE new overshot wheel at the Mnrchie mine, built by J. B. Flack, is 7 feet breast, 125 feet in diameter, and runs, with 150 inches of water, a 50-stamp mill. It cost $2,000, including housing; and as the company has its own water for eight months in the year, it will effect a saving of $25 per day.

MR. J. S. PHILLIPS has fitted up offices, for instruction in the various departments of mining and assaying, at No. 702 California street, opposite the Acedemy of Sciences' building.

ON FILE.—Letter, aecompanying specimens, from S. A. L., Long Valley.

DEWEY & CO.

American & Foreign Patent Agents

OFFICE, 202 SANSOME ST., N.E.COR. PINE, S. F.

PATENTS obtained promptly; Caveats filed expeditiously; Patent Reissues taken out Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; Every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure, with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Baden, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurtemburg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Granada, Chile, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established.

Our schedule price for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We *can and do* get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country) SOONER than any other agents.

The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more correctly judge of the value and pateutability of inventious discovered here than any other agents.

Situated so remote from the seat of government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars free.

Home Counsel.

Our long experience in obtaining patents for Inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing to them the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applicants which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents or purchasers of patented articles, can often receive advice of importance to them from a short call at our office.

Remittances of money, made by individual invcntors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money, but their inventious also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency.

Engravings.

We have superior artists in our own office, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

DEWEY & CO.

United States and Foreign Patent Agents, publishers Mining and Scientific Press and the Pacific Rural Press, 202 Sansome St., N E. corner Pine, S. F.

GOOD LAND

—IN A—

FAVORABLE LOCATION,

GUARANTEEING

Sure Crops Every Year.

The Reading Ranch,

In the Upper Sacramento Valley, originally embracing over 26,000 acres of

Choice Grain, Orchard and Pasture Land,

Is now offered for sale at low prices and on favorable terms of payment,

In Sub-Divisions to Suit Purchasers.

The ranch was selected at an early day by Major P. B. Reading, one of the largest pioneer and owners in California. It is situated on the west side of the Sacramento River and extends some 20 miles along its bank.

The average rainfall is about 30 inches per annum, and crops have never been known to fail from drouth.

The climate is very healthful and comparatively desirable. The near proximity of high mountain peaks gives cool nights during the "heated terms" which occur in our California summers.

Soft well water—remarkably sweet, pure and healthy—is obtainable at a depth of from 15 to 35 feet.

Wood is plentiful and easy to get.

Figs, Grapes, Peaches, Prunes, Almonds, English Walnuts, Oranges and other temperate and semi-tropical fruits can be raised with success on most of the tract. Also, Vegetables, Corn and all other cereals ordinarily grown in the State.

A considerable amount of the rich bottom land has already been cultivated.

Deep Soil With Lasting Qualities.

The soil throughout the tilled portions of the ranch proves to be of great depth and enduring in its good qualities. It is quite free from foul growths. The virgin soil among the large oak trees on the bottom land is easily broken up and cultivated.

The California and Oregon railroad traverses nearly the entire length of the tract. There are several sections, stations and switches, besides depots at the towns of Anderson and Reading—all of which are located within the limits of the ranch.

Land suitable for settlers in colonies can be obtained on good terms.

Are offered for sale in Reading, situated on the Sacramento River, at the present terminus of the railroad. It is the converging and distributing point for large, prosperous mining and agricultural districts in Northern California and Southern Oregon. Also, lots in the town o Anderson, situated more centrally on the ranch. Lots in both these towns are offered at a bargain, for the purpose of building up the towns and facilitating settlement of the ranch.

Purchasers are invited to come and see the lands before buying here or elsewhere. Apply on the ranch, to the proprietor,

EDWARD FRISBIE,
Anderson, Shasta Co., Cal.

Pocket Map of California and Nevada.

Compiled from the latest authentic sources, by Chas. Drayton Gibbs, C. E. This map comprises information obtained from the U. S. Coast and Land, Whitney's State Geological, and Railroad Surveys; and from the results of explorations made by R. S. Williamson, U. S. A., Henry Degroot, C. D. Gibbs and others. The scale is 18 miles to 1 inch. It gives the Judicial and U. S. Land Districts. It distinguishes the Townships and their subdivisions; the County Seats; The Military Posts; the Railroads built and proposed, and the limits of some of them; the occurrence of gold, silver, copper, quicksilver, tin, coal and oil. It has a section showing the hights of the principal mountains. The boundaries are clear and unmistakable, and the print good. 1878. Sold by DEWEY & CO. Price, postpaid, $2; to subscribers of this journal, until further notice, $1.

BUYER

—AND—

COMMISSION MERCHANT.

The undersigned, after an experience of forty years in the Grocery Business, has opened an office at No 24 CALIFORNIA STREET, corner Drumm, for buying and selling all kinds of Goods. Parties throughout the States and Territories wishing an Agent in this Market for the transaction of their business, by entrusting the same to me, I can have special rates made, with full guarantee of satisfaction, or no charge for services.

With twenty-five years' experience in this Market, I think I can suit one and all, both as a buyer and seller. All I ask is a trial. I will also have a Ladies' Department, under the management of a lady of experience and taste, who will fill all orders for your wives and daughters. Orders for this this Department should be endorsed: "For Lady Buyer."

All parties ordering will be required to send funds with order or satisfactory reference. Respectfully,

WHEELER MARTIN,
24 California Street, San Francisco.

REFERS BY PERMISSION.

WELLS, RUSSELL & CO.,
Mechanics' Mills, Cor. Mission and Fremont Streets.

CAUTION

To Hydraulic Miners.

The public generally and Hydraulic Miners especially are hereby notified that any parties making or using the contrivance known as the HOSKIN DEFLECTOR will be prosecuted to the full extent of the law, said machine having been declared by the U. S. Circuit Court an infringement upon my patent, the

Bloomfield Deflecting Nozzle.

The public are also cautioned against using the Hoskin Deflector because of its danger to life and limb, this device having already occasioned several deaths and other serious accidents. The BLOOMFIELD DEFLECTOR is entirely safe, its two and a half years use without accident, as well as its construction, proves it to be a reliable contrivance.

Any parties wishing to purchase the right to use these Deflectors can do so by applying to the undersigned,

HENRY C. PERKINS,
North Bloomfield, Nevada Co., Cal., October 1st, 1878.

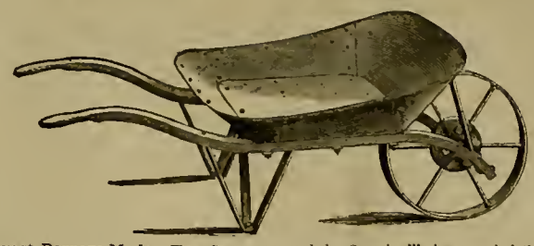
FRANCIS SMITH & CO.,

MANUFACTURERS OF

THE PATENT CHANNEL IRON WHEELBARROWS,

SHEET IRON PIPE.



SHEET IRON PIPE.

The Strongest Barrow Made. These Barrows are made by Superior Workmen, and of the best material. All sizes kept constantly on hand.

Lap-Welded Pipe, all Sizes, from Three to Six Inches. Artesian Well Pipe. Also, Galvanized Iron Boilers, from Twenty-five to One Hundred Gallons.

Iron Cut, Punched, and Formed for making pipe on ground, where required. All kinds of tools supplied for making pipe. Estimates given when required. Are prepared for coating all size of pipes with a composition of Coal Tar and Asphaltum.

Office and Manufactory, 130 BEALE STREET, San Francisco, Cal.

In consequence of spurious imitations of

LEA AND PERRINS' SAUCE,

which are calculated to deceive the Public, Lea and Perrins have adopted A NEW LABEL, bearing their Signature, thus,

Lea Perrins

which is placed on every bottle of WORCESTERSHIRE SAUCE, and without which none is genuine.

Ask for LEA & PERRINS' Sauce, and see Name on Wrapper, Label, Bottle and Stopper. Wholesale and for Export by the Proprietors, Worcester; Crosse and Blackwell, London &c., &c.; and by Grocers and Oilmen throughout the World.

To be obtained of CROSS & CO., San Francisco.

SAVE YOUR GOLD!

Highly Important to Miners and Quartz Mill Men!

SILVER PLATED COPPER AMALGAMATING PLATES.

The BEST PROCESS yet discovered for SAVING FINE GOLD. Extensively used in Mines and Quartz Mills. Over FIVE HUNDRED ORDERS have been filled for these Plates.

Inventors, model makers and amateur mechanics and students, will find the work valuable far beyond its cost. Sold by DEWEY & Co., Patent Agents and publishers of MINING AND SCIENTIFIC PRESS, San Francisco. Price, $1, (post paid.

Continued from page 53.

duced as it was from ore which was taken from the lowest levels of the company's mine, it proves that the deeper we go the more gold the ore contains. The Winthrop company are pushing their tunnel into the mountain as fast as possible, and when they cut their ledge at this depth you may look for a general jubilee in Copper City, as it is well known that this mine contains the richest ore ever found in this district.

TRINITY.

RETURNED.—*Journal*, Jan. 17: E. B. Barnum, of Taylor's Flat, accompanied by Archie McDonald and the latter's son, returned from San Francisco last week. Mr. Barnum thinks he will be able to dispose of his mining property to the company that has lately been contemplating its purchase.

MINING affairs are entirely frozen up and consequently stagnant. More storm and an old-fashioned January thaw are needed to make mining operations active.

TUOLUMNE.

THE MARKS & DARROW MINE.—*Independent*, Jan. 18: We were recently shown some exceedingly rich ore from this mine by one of the Darrow brothers, the gold being disseminated throughout the quartz; the quartz being a fine quality and taken from different parts of the mine. We have visited the property several times, and our opinion has never changed to disfavor, as it has all the indications of permanency and great wealth. The mine is located on the mother lode, well defined, with numberless rich feeders which will pay handsomely to work. It is not one of the mines of short continuance, for Gen. Darrow and his sons, who were the discoverers and locators, have worked it for many years; and when the old General wanted a political stake, or "grub" money, he would, with the assistance of the boys, go to pounding in hand-mortars, and in this manner they have taken out thousands of dollars. It is located in a rich mining section; the gulches, canyons, creeks and ravines have proven to be immensely rich in the region from the grinding down of these common carriers of gold. Tuolumne has been one of the richest placer mining counties in the State, and as it has been proven that quartz is the mother of gold, it therefore augurs well for our numerous quartz ledges. If capital would take hold of a few such mines in our county it would infuse new life to our camps and bring prosperity to every one.

YUBA.

TUNNELS.—Nevada City *Herald*, Jan. 18: The Yuba River mining company have run a tunnel 300 feet under the river at Long Bar, and struck gravel which pays $3 to the pan. This is the pioneer mining enterprise of what promises to be a success in reaching the beds of the present river channels. The following claims are located for that purpose along the Yuba river: Yuba, Long Bar, West Point, Nichols' claim, Olmstead, North Star, Sand Flat, Ohio and Tennessee. These companies are all corporations, and the larger part of the stock is held in Grass Valley. There are many places under the late river channels which have never been worked. The tailings from the larger mining operations above coming down and covering them up. Formerly miners tried working these places by wingdams and other contrivances to turn the water when it was low, but the debris has become so deep that it took nearly all summer to get down where the good pay was, and then the high water would come and wash away the dams and fill up the holes so that the same work would need to be repeated each summer, and the gravel has become so deep in the modern river beds that it made the seasons too short to enable advantageous work. Now a shaft is sunk on the bank and tunnels are run under the river bed, in search of the pay gravel.

NEVADA.

WASHOE DISTRICT.

SIERRA NEVADA.—Gold Hill *News*, Jan. 22: The foundations for the new air compressor are completed ready for the machinery. The diamond drill in the face of the north drift on the 2200 level has penetrated a distance of 250 feet without finding more than a very slight flow of water. The drill has been taken out and the drift again started up. It will be now pushed directly ahead to connect with the east drift from the 1700 level. Sinking the main incline is making steady progress, the bottom still being in the same favorable character of cap rock heretofore described. It is now down 151 feet on the slope below the 2200 station, and will have only about 16 feet further to go to reach the 2300 level.

CROWN POINT.—The east drift from the winze on the 2300 level is in to-day 462 feet, the face still in very favorable vein matter. The vein at this point has great width, there being no signs whatever of the east wall as yet. The entire stratification of the rock lying next to and west of the ore vein on this level appears to be straightening up and assuming a more perpendicular strike.

CON. IMPERIAL.—The south incline winze, below the 2400 level, has reached a depth of 2600 feet, at which point a station is being cut out preparatory to running drifts both north and south on the ore vein.

GOULD & CURRY.—Crosscuts Nos. 2, 3 and 4 east, on the 1900 level, are all making good headway, without any change of value to report. A joint crosscut west has been started from the bottom of the joint Savage winze.

BEST & BELCHER.—Sinking the Osbiston shaft has made slow headway during the past week on account of the continuous flow of water. The new hoisting engine is working finely.

OVERMAN.—Everything in and about the mine is working finely.

OPHIR.—Daily yield, 75 tons of ore. The stopes on both the 1900 and 2000 levels continue to yield rich ore.

JUSTICE.—A large supply of ore has been extracted and delivered at the mill ready to crush when needed.

CALIFORNIA.—Daily yield, 340 tons of ore. This ore is being extracted from the 1750 and 1650 levels. The ore is of a good quality, and the stopes continue to look well. Another large lift pump is being put in at the 2150 station. As soon as that is completed, which will be in six or seven days, sinking the C. & C. shaft will be resumed.

CHOLLAR-COMBINATION SHAFT. — The new pumps have been running the greater part of the week pumping water into the Sutro tunnel. Everything working with the greatest perfection.

BELCHER.—The south drift on the 2360 level is being pushed rapidly ahead. It is now in 544 feet. The east drift at the 2560 station is being pushed rapidly ahead, the face in west country rock that blasts out and works well.

BULLION.—The north drift on the 2000 level is making good progress and will complete a connection with the main incline in three or four days more. The face is in a mixture of quartz and porphyry of a fine character.

NORTH CONSOLIDATED VIRGINIA.—The new machinery for the mine is beginning to arrive by the car-load, and will all be on the ground ready to place in a very short time.

HALE & NORCROSS.—The week has been mostly spent in putting in the connecting station at the combination shaft, running drifts and sinking a winze at that point to connect with the water tank 30 feet below the station, laying pipes and getting ready generally for sending a flood of hot water through the Sutro tunnel.

CON. VIRGINIA.—Daily yield, 80 tons of ore, which is being reduced as it is extracted. This ore is taken mostly from the 1500 and 1400 levels. The west drift on the 2150 level is in 147 feet, the face in hard blasting porphyry. A new lift pump is being put in at the 2150 station. As soon as that is completed, sinking the main shaft will be resumed.

JULIA CON.—Repairing the main south drift on the 1800 level is making better progress, the drift being less caved, and the necessary repairs consequently much lighter. The heat in this drift is intense, being so great at times that it is all the most hardened of miners can do to stand it.

SUTRO TUNNEL.—Owing to the great heat the progress of the south lateral branch toward the Julia shaft is somewhat retarded, but it ought to reach and connect with the shaft in the course of a week or 10 days. Nothing definite can be said regarding the use of the main tunnel as a drain for the mines until pending negotiations can be concluded between the mining companies and the tunnel company.

YELLOW JACKET.—The new shaft is now down 3192 feet; ground hard, but working well. No water to interfere.

SAVAGE.—On the 2100 level the south drift from the bottom of the north winze is steadily advancing, with the face in a fine, favorable character of quartz and vein matter.

UTAH.—The new powerful hoisting engine will be in readiness to start in 15 days more, if no unusual delay occurs.

ARIZONA.

COAL.—*Sentinel*, Jan. 18: The discovery is reported of coal beds in the northwestern part of the State of Sonora, at no great distance from the southern boundary of Yuma county. We have before heard similar reports, but investigation proved the mineral to be obsidian in one case and cobalt in another. This time, however, the discovery of genuine coal is announced by parties who are competent judges of the article, and who claim to have proved its character by combustion.

THE Enterprise mine, Pinal mountain, owned by Tweed & Hale, shows a five-foot vein. The approximate value for the whole width is about $150; the assays from $40 to $500 per ton. The shaft is now down 43 feet.

COLORADO.

SAN JUAN.—Leadville *Eclipse*, Jan. 2: One of the most successful furnaces in Colorado is that of the Norfolk & Ouray company, at Ouray, in San Juan. The operations of the company were commenced in the summer of 1876, by M. S. Corbett, who is Superintendent. A few weeks since the company purchased for $75,000 the very valuable property, at Ouray, known as the Begole mineral farm. The construction of the furnaces were put under the charge of W. H. Strout. With 25 men at work on the mineral farm it is expected to run the entire winter with that ore and what is now on hand from the other mines of the company. The capital for the building of the furnace and the purchase of the mines has been furnished by parties at Norfolk, Va. It is expected that the profits for the first year in which the furnace will be run will be sufficient to reimburse the outlay. The mines and furnaces are valued at $2,000,000.

LEADVILLE.—In the first year of its existence Leadville yielded nearly [$4,000,000—from 30 mines situated within a space of two miles square. A smelting company has organized in Illinois for the purpose of treating Leadville ores, and through an agent have secured six acres of land on the Oro company's placer ground at the west end of the town, on which to erect buildings.

IDAHO.

SALMON FALLS.—Cor. Salt Lake *Tribune*, Jan. 5: We have a district formed here called the Salmon Falls mining district, running from the mouth of the Malad to Payne's Ferry, taking both sides of the river for four or five miles. Mr. Davis, who is superintendent of the Cave & Davis bar, at the falls, has his machine almost finished, and expects to commence operations about New Years. Morrow, of the Morrow & Jacob's bar, is here getting things ready on their claim, and digging a ditch to put up plates as soon as the road opens in the spring. There are two other districts formed on the river, one above, reaching to the famous Shoshone falls, and taking in that most wonderful canyon with perpendicular walls 400 feet high, and where men in 1869-70 made as high as $100 a day to the man with a rocker, a copper plate and a bottle of cyanide of potassium. The other district is the Eureka, below us, in both of which there are new locations made every day. By the way, there were men who made $9 per day to the man at Payne's Ferry, the upper end of our district, and Wickham and Donovan, with a small beach machine and a few sluice boxes, have been averaging $15 to the man ever since they started up last February.

FLORIDA MINE.—*Idaho Avalanche*, Dec. 28: The first crushing of unassorted rock made the handsome yield of $62 to the ton.

BURNT RIVER.—The placer mines are good on Chicken creek. They have completed a ditch eight miles long at a cost of $5,000. Ten claims are being prospected, and will pay $10 per day to the hand.

SOUTH MOUNTAIN.—J. M. Brunzell returned here from South Mountain on Thursday. He states that the place is alive with men who are locating new claims and relocating old ones.

UTAH.

ONTARIO MINE.—Salt Lake *Tribune*, Jan. 1: Last July a new shaft was started north of and about 310 feet from the old shaft. This has two hoisting compartments of 4½x5 feet each, and one pump compartment 5x7 feet, and is now down on a level and connected with the 500 level of the mine by a 247-foot crosscut. On the new shaft is erected the new hoisting and pumping works, 100 feet in length by 50 feet in width, and the hight above the gallows frame over the shaft is 65 feet. These works were designed by Messrs. Salkeld & Eckart, of Virginia City, Nevada, and erected under the personal supervision of Mr. Salkeld and James McMillan, his foreman. As soon as the water is out of the mine this shaft is to be continued for 100 feet more, and a level started east and west on the ledge. It is expected that the works will be completed and the extraction of ore commenced the latter part of this month. Although the old works of the Ontario company were destroyed by fire on the 19th of October last, they have continued paying dividends, as they happened to have on hand at the mill a lot of 2,500 tons of ore. The yield of the mine for 1878 was $1,445,766.83.

OLD PROBABILITIES.—The Eastern weather god has finally undertaken to fix up the weather for the Pacific coast. His first utterances are as indefinite as the Delphian oracles, and will probably suit all cases. He begins by prognosticating for the coast in three divisions, lower, central and upper, which may, we presume, embrace all the coast line from Aspinwall to Alaska; and thus having a wide mark, he may hit somewhere, as the boy thought when he fired at the barn. However this may be, we doubt not the Signal Service will localize their prophesies as fast as possible, and the difficulties of the problem they encounter will permit. It is true that our meteorological conditions seem so grouped in grand divisions that there will be a degree of monotony in the daily forecasts, but there are certain periods when a foreknowledge of coming rain will be of great value to our agriculturists and warning of approaching storms, will always help the mariners. One point of especial importance to the agriculturist, is the coming of the October rains. At that season of the year, the raisins and other drying fruits are exposed, and a day's warning of rain would be worth thousands of dollars to the producers. As these interests are yearly increasing, the value of the warning will proportionately increase, and we trust that it may be forthcoming. There will doubtless be other practical and important applications of the information as soon as it assumes the definiteness attained at the East, and we are glad that our coast has been embraced in the system.

A DISPATCH from Pendleton, dated 17th, via Walla Walla, the 18th, says: "Aps, the remaining Indian convicted of complicity in the murder of whites last summer, was hanged here to-day. The same precautions were observed to prevent trouble. A number of whites and Indians attended the execution. Several prominent Indians addressed the whites, assuring them of peace in the future. Two hours before the execution, 'Aps' bid farewell to his people. He said he died as an innocent man; he had killed no one; abjured his people to profit by his fate, to always remain steadfast friends to the whites and not harbor ill feeling towards them."

WHAT AND HOW?

In this column are printed all sensible inquiries relating to and connected with mining or relating to any matters of general scientific interest; also the answers to them as dictated by individual experience, or as furnished by correspondents.

Practical Questions in Hydraulic Mining.

S. S. H., of Leadville, Colorado, writes that he is in need of information on the following questions:

"What is the heaviest grade per mile that can with safety be given to a ditch to carry 5,000 miners' inches of water, running through firm gravel and loam? (California experience preferred).

"How many cubic yards of light gravel would a four-inch giant move, having 100 feet heads, in 12 hours?

"Will you please be so kind as to give me the address of a few hydraulic mining engineers and mining superintendents of practical experience in managing placer mines?"

In loam, you should not exceed eight feet to the mile. Gravel will bear almost any grade, depending upon its consistency. If uncemented, and containing large boulders, the grade may be between 8 and 16 feet, or even more. Although data have been published in regard to the execution of water under similar circumstances (see Waldeyer in Raymond's reports, about 1873. Bowman's report on the California Water Company's operations in the Georgetown divide, and Bowie's treaties on Hydraulic Mining), the outlet grade, and some other particular conditions that may be implied in your questions, would have to be particularly stated. Hamilton Smith or Mr. Perkins, of the N. Bloomfield Co.; Daniel McGanny or G. P. Thurston, of the Smartsville Co.; Jos. McGillivray or Herman Schussler, of San Francisco; or either of the authors of the reports mentioned, will answer your questions correctly, if you will specify all the essential conditions.

THE ICE BRIDGE AT NIAGARA.—Niagara river below the falls is spanned by a bridge of ice one mile long and 60 feet wide. The river has been spanned in this way before, but seldom, if ever, so early as now. The other day the ice "jammed" beneath the upper suspension bridge. Says the Buffalo *Courier:* A vast quantity of water had accumulated behind the ice and made a desperate effort to get free. The enormous body of snow and ice was raised up by the water and tossed about in all directions. Large blocks, weighing hundreds of tons were lifted into the air. Boulders were torn from the shore and swept into the stream, and a solitary fir tree, which ordinarily stands three feet above high water, was carried away. The pondering strength of the enraged waters was so apparent that it seemed as if they would rend the great gorge in twain, and in that way escape from their imprisonment. As they could not break the mile-wide dam in two, they lifted it bodily into the air and rushed away beneath it, leaving a span of ice above and behind them. The formation of the ice in this bridge is not the same on both sides of the river. On the American side it is chiefly composed of snow formed into rounded boulder shapes, and looks like white coral. As one approaches the center of the river the ice fragments become larger, and near the Canadian shore huge cakes of water-ice are formed into a solid mass. In some places there are crevices 25 or 30 feet in depth, but water is not seen through them.

IN the District Court at Marysville Monday morning, Ah Ben, through an interpreter, pleaded guilty of murder in killing McDaniel in October last. Monday next is set to hear testimony and fix the degree of punishment. Ah Gee, charged with murder in killing a Chinaman on Yuba River bridge, was arraigned, and Wednesday set to plead.

F. E. DAVIS, of San Francisco, and F. W. Stone, from Australia, ran a 100-yard race for a purse of $1,000, in this city. Davis won in 10½ seconds. In Ukiah a 100-yard foot race was won by Bill Cramer, of that place, in the good time of 10 seconds, beating Joe Barbor, of Lake county, about 10 feet.

SAYS the Dixon *Tribune* of Saturday: Most of the orange trees in town which were last week supposed to be dead, will come out all right. In fact, the orange trees appear to stand it better than the gum trees.

THE District Court, in Calaveras county, which meets the latter part of this month, will have to try five indictments for murder. Among the accused are four Chinamen, an Indian and one white man.

PERSONAL ADORNMENT. — The number of people who have drawn upon the stock of Palmer Bros., for their handsome clothing, underwear, toilet articles, etc., during the last few weeks, is beyond count. The firm, at their establishment 726 to 734 Market street, have a splendid variety of goods to choose from, and one can hardly go amiss in seeking everything necessary for personal adornment and comfort at their store.

PATENTS AND INVENTIONS.

News in Brief.

THE ice gorges in the James river have broken up.

THE charter of the Louisiana lottery has been repealed.

THE distress among workingmen in England increases daily.

THE jail at Pine Bluff, Ark., was fired by a prisoner Saturday night and destroyed.

THERE were 103 deaths from scarlet fever in New York last week, against 274 the week before.

THE popular vote in Switzerland gives a large majority in favor of a subvention to Alpine railways.

THE Upper Columbia river is almost clear of ice, and boats will commence making regular trips.

AN attempt was made recently in Candabar to assassinate Major St. John, of the British army.

THE Zulu King expresses a willingness to accede to some of the demands of the British ultimatum.

A PHILADELPHIA dispatch announces the death of John B. Biddle, Dean of Jefferson college.

CAPT. JOHN IRWIN has been ordered to the command of the receiving ship *Independence* at Mare Island.

AN indictment has been found in Florida against Lieutenant-Governor Hull, on a charge of conspiracy.

THE Sub-Treasury building in New York, is being fortified against any raid upon its treasure in case of a riot.

IN a collision off the coast of Spain, the British sailing vessel *Lancashire Witch* sunk with all on board.

THE recent report relative to Germany's intended action towards the Samoan Islanders is denied from Berlin.

THE Directors of the City of Glasgow bank are on trial at Edinburgh, charged with fraud, theft and embezzlement.

THE indirect taxes of France during 1878 yielded a revenue of 2,025,770,000 francs—an increase of 75,672,400 francs.

ANDRE CHRISTOL, the wrestler, had his collar bone broken at Detroit, Saturday night, in a match with J. H. McLaughlin.

SIX cotton mills at Preston, Eng., running 188,144 spindles, have given notice of a reduction in wages of from 5% to 10%.

JOHN G. COMPTON, ex-postmaster of Columbus, Neb., has been sentenced to 10 years' imprisonment for robbing the mails.

A JUDGE OF ELECTION in Baltimore has been fined $100 and four months' imprisonment for assaulting a Deputy United States Marshal.

IN sinking a well at Ione, Amador county, recently, James Parkison struck a vein of coal, through which he has already bored six feet, without exhausting it.

J. A. JOHNSON, Secretary of the Constitutional Convention, has tendered his resignation. It was accepted, and Ed. F. Smith was chosen as Secretary in his place.

LADIES AND GENTLEMEN are both alike provided for by Palmer Bros., in all things fitted to give satisfaction and comfort in the way of clothing, furnishing goods, laces, millinery, and the 1,000 articles needed in fitting up the "human form divine." You can supply your whole family at little expense, by consulting Palmer Bros., at 726 to 734 Market street, S. F.

FRESH attractions are constantly added to **Woodward's Gardens**, among which is Prof. Gruber's great educator, the Zoographicon. Each department increases daily, and the Pavilion performances are more popular than ever. All new novelties find a place at this wonderful resort. Prices remain as usual.

SETTLERS and others wishing good farming lands for sure crops, are referred to Mr. Edward Frisbie, of Anderson, Shasta County, Cal., who has some 15,000 acres for sale in the Upper Sacramento valley. His advertisement appears from time to time in this paper.

EXAMINE the accelerative endowment plan, as originated by the Mutual Benefit Life Insurance Co., of Newark, New Jersey. Assets, $30,533,429.94. Lewis C. Grover, President; L. Spencer Coble, Vice-President; Benjamin C. Miller, Treasurer; Edward A. Strong, Secretary; Bloomfield J. Miller, Actuary. Send for circulars to James Munsell, Jr., agent of insured, 224 Sansome St., San Francisco.

EXPERIMENTAL MACHINERY, drawings, patterns, models, all kinds of electrical and telegraphic apparatus to order. See ad. F. W. FULLER, 415 Market St., second floor, S. F.

HENRY R. EWALD is our general correspondent and agent for Arizona.

Total rain during the season, from July 1, 1878, 4.37 in.

We have on hand some 400 to 500 lbs. of brevier, in good condition, for sale at a bargain. Will sell a part only if desired. Second-hand cases to match. Also a font of bourgeois in first-rate order, with cases. Also a cabinet and upwards of twenty fonts of good display type, not very old and but little used. Some of the fonts are large,

Printing Type For Sale Very Low.

of modern style, and what might be termed good substantial display type for advertisements and job printing.

A good proof press will also be sold at a greatly reduced price from cost.

We can fit out a good country printing office nearly complete at a moderate cost. Call and see the material.

DEWEY & CO.,
Publishers, No. 202 Sansome street, San Francisco.

Patents for Mining and Farming Lands.

Having complete arrangements with competent and reliable parties in Washington City, by which we are able to secure prompt and careful attention to law business there, we are prepared to assist Mill and Mine, Canal and Ditch owners in securing patents for their lands, mines and claims, in addition to our general line of patent business.

Many who are acquainted with the manner in which this business has heretofore been conducted, (with or without assistance by local attorneys), will see at once the great advantage of patronizing an establishment that is thoroughly organized and has its representatives in Washington to look after and prosecute their applications before the Commissioner of the General Land Office. The business on this Coast will be attended to personally by a member of our firm, and satisfaction will be given in all respects.

Correspondence from persons desirous of securing patents for Lands, Mines, Mill Sites, Canal and Ditch property, promptly attended to.

Applicants for patents for mining and farming land, whose claims have been delayed for any reason, will find it to their advantage to consult with us and in case of necessity secure the services of our home and Washington branch agency.

DEWEY & CO.,
Solicitors of Patents for Lands, Mines and Inventions, MINING AND SCIENTIFIC PRESS OFFICE, No 202 Sansome St., San Francisco

WATSONVILLE, July 29th, 1873,
MESSRS. DEWEY & CO.—*Gents:*—I was not expecting my patent so soon. You certainly kept your word when you said no time would be lost. I remain, yours truly,
W. T. EASTERDAY,

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

Cherokee Flat Blue Gravel Company.—

Location of principal place of business, San Francisco, California. Location of works, Cherokee Flat, Butte County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 20th day of December, A. D., 1878, an assessment (No. 40) of five cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the Company, 318 Pine street, Room 6, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 28th day of January, 1679, will be delinquent, and advertised for sale at public auction; and unless payment is made before will be sold on Tuesday, the 18th day of February, 1879, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors. R. N. VAN BRUNT, Secretary.

Office, 318 Pine Street, Room 6, San Francisco California.

Griffith Consolidated Mill and Mining Company

—Location of principal place of business, San Francisco, California. Location of works, Diamond Springs Mining District, El Dorado County, California.

Notice is hereby given, that at a meeting of the Board of Trustees, held on the 21st day of January, 1879 an assessment (No. 1) of twenty cents (20c) per share was levied upon the Capital stock of the Corporation, payable immediately to the Secretary, at the Office of the Company, Room 48, 330 Pine Street, San Francisco, California.

Any Stock upon which this Assessment shall remain unpaid on the 26th day of February, 187·, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on Wednesday, March 26th, 1879, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Trustees. GEO. M. CONDEE, Sec'y.

Office, Room 48, 330 Pine Street, San Francisco, California.

Mariposa Land and Mining Company of

California.—Location of principal place of business, San Francisco, California. Location of works, Mariposa County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the tenth day of January, 1879, an assessment (No. 15) of One Dollar per share was levied upon the capital stock of the corporation, payable immediately in U. S. currency to the Secretary, at the office of the Company, Room 33, Nevada Block, No. 309 Montgomery St., San Francisco, Cal., or the Assistant Secretary at the office No. 9 Nassau St., New York, N. Y.

Any stock upon which this assessment shall remain unpaid the twelfth day of February, 1879, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on Wednesday, the twelfth day of March, 1879, to pay the delinquent assessment, together with cost of advertising and expenses of sale. By order of the Board of Directors. LEANDER LEAVITT, Sec'y.

Office, Room 33, Nevada Block, No. 309 Montgomery St., San Francisce, Cal.

Summit Mining Company.—Location of

Principal place of business, San Francisco, California. Location of works, Mineral Point Mining District, Plumas County, Cal.

NOTICE.—There are delinquent upon the following described stock, on account of assessment (No. 6,) levied on the 19th day of November, A. D., 1878, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Certificate.	No. Shares.	Amt.
Boring, I C	32	1200	$60 00
Bohn, John	150	200	10 00
Lehmann, C	129	2750	137 50
Lehmann, C, Trustee	206	200	10 00
Lehmann, C, Trustee	207	200	10 00
Storer, J F, Trustee	58	250	12 50
Schmitz, F	205	400	20 00
Turner, J W	65	200	10 00

And in accordance with law, and an order of the Board of Directors, made on the nineteenth day of November, A. D., 1878, so many shares of each parcel of such stock as may be necessary, will be sold at public auction, at the office of the company, No. 318 Pine street, Room 6, San Francisco, Cal., on Tuesday, the fourth day of February, A. D., 1879, at the hour of three o'clock P. M., of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of the sale.

R. N. VAN BRUNT, Sec'y.

Office, Room 6, No. 318 Pine Street, San Francisco, Cal.

UNITED STATES
Mineral Land Laws, Revised Statutes
AND INSTRUCTIONS AND FORMS UNDER THE SAME.

We have just issued a pamphlet containing the General Mineral Land Laws of the United States, with instructions of the Commissioner of the Land Office. The contents of this pamphlet comprise all of the Government laws with relation to mineral lands of interest to the mining community, as follows: Mining Statute of May 10th, 1872, with Instructions by the Commissioner of the Land Office; Mining Statute of July 26th, 1866; Mining Statute of July 9th, 1870. Forms required under Mining Act of May 10th, 1872, as follows: Notice of Location; Request for Surveys; Application for Patent; Proof of Posting Notice and Diagram of the Claim; Proof that Plat and Notice remained Posted on Claim during Time of Publication; Registers' Certificate of Posting Notice for Sixty Days; Agreement of Publisher; Proof of Publication; Affidavit of $500 Improvements; Statement and Charge of Fees; Proof of Ownership and Possession in Case of Loss or absence of Mining Records; Affidavit of Citizenship; Certificate that no Suit is Pending; Power of Attorney; Protest and Adverse Claim; Non-Mineral Affidavit; Proof that no Known Veins Exist in a Placer Claim, etc. There is also given the U. S. Coal Land Law and Regulations thereunder. The work comprises thirty pages, and will be sold, post-free, for 50 cents. It should be in the hands of every one having any mining interests. DEWEY & CO.,
Publishers of the MINING AND SCIENTIFIC PRESS, S. F

STEAM BOILERS. Particular attention given to the quality of the material and workmanship, and none but first-class work produced.

SUGAR MILLS AND SUGAR-MAKING MACHINERY made after the most approved plans. Also, all Boiler Iron Work connected therewith.

WATER PIPE, of Boiler or Sheet Iron, of any size made in suitable lengths for connecting together, or sheets rolled, punched, and packed for shipment ready to be riveted on the ground.

HYDRAULIC RIVETING. Boiler Work and Water Pipe made by this establishment, riveted by Hydraulic Riveting Machinery, that quality of work being far superior to hand work.

SHIP WORK. Ship and Steam Capstains, Steam Winches, Air and Circulating Pumps, made after the most approved plans.

PUMPS. Direct Acting Pumps, for Irrigation or City Water Works purposes, built with the celebrated Davy Valve Motion, superior to any other Pump.

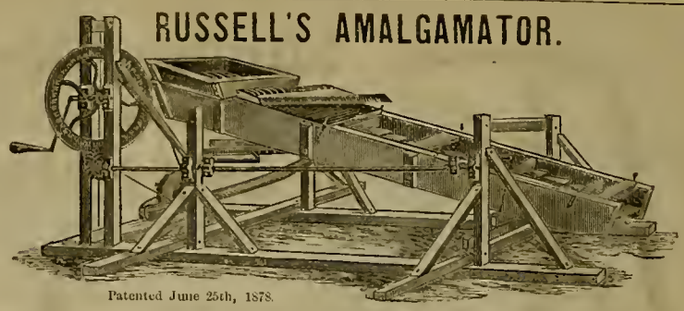
RUSSELL'S AMALGAMATOR.



Patented June 25th, 1878.

SAVE YOUR GOLD

And Also SAVE YOUR QUICKSILVER.

The above Washer and Amalgamator with new patent Wire Bridge Quicksilver Boxes attached, can be worked wet or dry, either by hand, steam, horse or water power, and is easily taken apart and packed. For washing Pulp, Earth, Gravel, Mill Tailings or Black Sand, it is without a rival.

Has been Thoroughly Tested and given Complete Satisfaction.

The entire Lining, Hanging Plates, Riffles and Boxes Amalgamated

IS GUARANTEED TO SAVE THE FINEST OR FLOAT GOLD.

Capacity, 30 to 60 tons per day, according to size. For further particulars apply to

J. MORIZIO, Gen'l Agt.,

Room 24, Safe Deposit Building, Corner Montgomery and California Streets, SAN FRANCISCO.

Ingersoll Rock Drills.

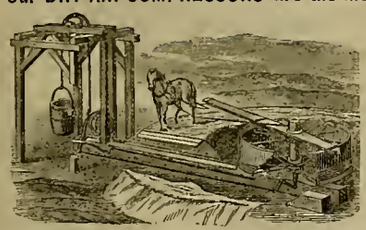
In use in the largest and best Mines of the Coast.

HAS AUTOMATIC FEED.

Has less Repairs.

Is Lighter and more Easily Adjusted than any other Drill.

Our DRY AIR COMPRESSORS are the most Economical Compressors in the Market.



MINERS' HORSE-POWER.

This Power is especially adapted to working mines, hoisting coal or building material, etc. It will do the work of a Steam Engine with one-tenth the expense. One Horse can easily hoist over 1,000 pounds at a depth of 500 feet.

The Power is mainly built of wrought iron, and cannot be affected by exposure. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued, wholesale and retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS Office, S. F.

BY GUIDO KUSTEL,

MINING ENGINEER AND METALLURGIST.

Roasting of Gold and Silver Ores, and the Extraction of their respective Metals without Quicksilver. 1870.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore.

It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus.

It is a work of great merit, by an author whose reputation is unsurpassed in his specialty.

Price, $2.50 coin, postage free.

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver Ores generally, with 120 Litbographic Diagrams. 1867.

This work is unequaled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Millman, Metallurgist, and other professional workers in ores and minerals, which cannot he found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery, etc., which alone are of the greatest value. PRICE, $7.50

Prompt Attention to Business.

Paul's Pulverizing Barrel.

ELECTRIC MILL, Butte Co., Cal.

ALMARIN B. PAUL.—*Sir:*—Yours requesting my opinion of your barrel, received. You can state I have used one for about three years, and that it has proved all you represented it to be. It does more good work, in reducing quartz fine, for less power and wear and tear, than any machine I know of. The simplicity of the barrel, the economy and perfectness of operation of the automatic feed and discharge, will satisfy anyone. I have run the barrel for weeks, day and night, without any stoppage whatever—only on Sundays. The barrel requires but very little attention—in fact no more than a stamp batery. I expect to soon send you an order for another.

Respectfully,
C. H. ROLLINS, Supt.

MINING AND SCIENTIFIC PRESS.

An Illustrated Journal of Mining, Popular Science and General News.

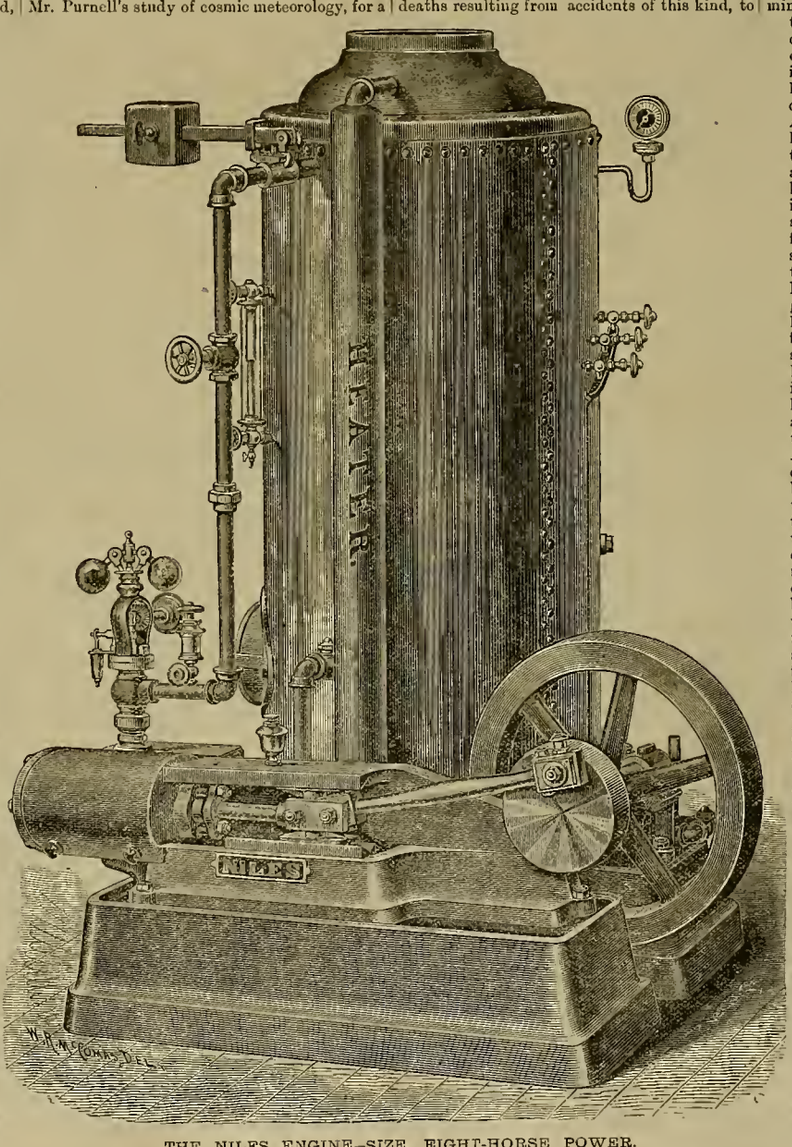
BY DEWEY & CO., Publishers. SAN FRANCISCO, SATURDAY, FEBRUARY 1, 1879. VOLUME XXXVIII Number 5.

The Niles Steam Engine.

The increasiug use of steam in various work pertaining to the industries of every day life is bringing out a class of smaller sized engines and boilers which are admirably adapted to the purposes for which they are designed.

The Niles engine, shown in the illustration on this page, is certainly of very handsome and symmetrical design, and it has points in its style of manufacture and the materials used, which commend it to attention. The size shown in the engraving is that ranked as 8-horse power, but there are smaller sizes and larger sizes made to suit the requirements of the user. The smallest engine is warranted to develop 2-horse power and the largest 12-horse power, with 60 pounds of steam pressure. The intermediate sizes are 4, 6, 8 and 10-horse power. The engine and boiler are mounted together upon a substantial cast-iron base, forming a complete power outfit. The engine is not attached to the boiler, but is erected on the same base with it. It is, therefore, not subject to the injurious effects of contraction and expansion. The bearings are not heated, and the lubricating oils are not baked on the working surfaces. Neither is the engine injured by vibration when running. Each engine above four horse-power is provided with a heater, into which the exhaust steam escapes; the feed water is heated up to nearly the boiling point (212°) before entering the boiler. The advantage of this is apparent, as it costs nothing to heat the water in this way. It produces a decided saving of fuel, and the injury to the boiler incident to injecting cold water is avoided.

The boilers are made of the very best material, entirely wrought-iron, and are of ample size to furnish the engine with steam when exerting its maximum power, having 15 square feet of heating surface per horse-power. No cast-iron whatever is used in its construction. The tubes are arranged for complete circulation, and are entirely below the water line, preventing the possibility of leakage. The trimmings are the best, comprising gauge cocks, glass water gauge, steam gauge, safety valve, check valve, blow-off cock and feed pump. The Niles engines are represented on this coast by Parke & Lacy, of 417 Market street, San Francisco, where the machines may be seen and examined by all interested.



THE NILES ENGINE—SIZE, EIGHT-HORSE POWER.

THE SIGNAL SERVICE.—We had the pleasure the other day of meeting Lieut. S. C. Vedder, of the U. S. Signal Service corps, who was on his way to Washington Territory to supervise the construction of a military telegraph line, over a route which Gen. Howard's late Indian campaign showed to be very desirable. We questioned Lieut. Vedder concerning the recent extension of "Old Probabilities" work to this coast, and he said it was the desire of the service to develop the system of prognostications and warnings on this coast as fully as they are now developed on the Atlantic side. There are, however, obstacles in the way, owing to the location and the inability of observers getting foreknowledge of the many storms which come unannounced from the seaward. However, it may appear that the system can be applied with full accuracy as soon as the Pacific coast conditions are better understood, through a longer period of observation. Thus far, during the few weeks which probabilities have been forwarded to this coast, they have proved gratifyingly correct and we have much confidence in the ultimate value of the work of the corps in the Pacific States. We urged upon the attention of the officer the great advantage it would be to our raisin and fruit drying interest to have announcement of the October rains, and he expressed a willingness to bring the matter to the attention of the authorities at Washington on his return from his northern mission. Lieut. Vedder is enthusiastically devoted to the work of the Signal corps and would be gratified to have it prove of as great value here as in the other parts of the country.

ASTROLOGY has in this last century of scientific progress fallen into the saddest disrepute of charlatanry. But such was not always the estimation in which the conjunction of the planets, and of the occult causes of the heavens, were regarded by the profoundest thinkers of the past. The Arabians astrologists were the originators of mathematics, and of the exact methods of dealing with the unknown quantities that gave birth to inductive science after many centuries. We direct the reader's attention to Mr. Purnell's study of cosmic meteorology, for a novelty to which he is leading—the possibility of a scientific reality in what has been hitherto known as astrology.

W. HOLMES, of the Hayden survey, reports the discovery of a large obsidian quarry near the head of the middle forks of Gardiner's river in the northwest of the Yellowstone National park. The deposits are nearly 600 feet thick, and the horizontal extent has not yet been ascertained.

EIGHT companies of troops will take the field in April to overawe the Indians, who are now acting sullenly.

Mining Accidents and the Lessons they Teach.

Having kept a partial list of the fatal accidents that have occurred in our mines during the past year, we find that these casualties aggregate a larger number than most persons would suppose. Our list is imperfect and fails to cover the whole of our mining territory, and yet it embraces not less than 65 or 70 cases of deaths resulting from accidents of this kind, to say nothing of the much larger number of men who have been wounded, or sustained other physical injury, often of a serious character. It is true that in noting these disasters we have not been called upon to record any of those fearful catastrophies that so often occur in the coal mines of England and other of the older countries, and in which hundreds of lives are sometimes sacrificed in an instant, or, what is worse, through the agonies and horrors of prolonged suffocation. As yet we have happily been spared these appalling disasters; the fire in the Yellow Jacket mine, in which some 20 or more lives were lost, approaching the nearest to them of anything that has occurred in our mining history. But considering how comparatively free our mines are from suffocating and explosive gases, the cause of most of these fatal accidents in the old countries, the annual loss of life on this coast is so deplorably large that we feel constrained to urge upon the attention of mining companies the necessity of adopting additional precautionary measures for diminishing their number in future.

From the imperfect record of these fatalities kept by us, we judge that the largest number of them is due to caves occuring in the stopes, drifts or other underground workings of the mines, not less than 15 having resulted from this cause the past year. Next in frequency comes deaths from blasts, premature and otherwise, their number for the year amounting to at least 10 or 12. Eight or ten men have been asphyxiated, dying from smoke or deadly gases accumulated in the mines. About an equal number have been killed by falling down inclines, shafts, etc., through the breaking or parting of ropes and cables, falling from buckets, etc. Several have been killed by rocks, timbers, etc., falling upon them while at work below, several also from overheat; one or two from cars descending upon them, etc. Besides the killed, a still larger number of these men have been wounded, some slightly, others sorely—not a few, in fact, so grievously that death itself would perhaps have been a better fate. When a man in the prime of life has his eyes blownout; is so crushed, dismembered and disfigured that he looses almost all semblance to humanity; is rendered for the balance of his days a helpless, sightless cripple, it were almost a mercy had he been killed outright, rather than he reduced to such a woful condition. And yet to this pitiful state a good many of these unfortunate men are every year brought. That they are entitled to universal commiseration none will deny, though there be those who affect to think that the wages of the miner might justly suffer a considerable reduction. And so, perhaps they might, if only the number of hours he works or the amount of labor he performs are to be taken into consideration. This, however, would be far from just. As the professional man is paid extra for his knowledge and skill, so should the miner be paid extra for the exposure of health and the danger to life and limb that in the prosecution of his duties he is forced to incur; and that his present rate of wages more than fairly compensates him for this additional hazard no right-minded employer will contend.

But while the employer should not grumble at the wages paid the miner, it would be well if the latter, in view of his dangerous occupation, were to exercise a little more prudence than is his wont, and endeavor to make better provision for his own wants, should he be thrown out of employment, or through accident be temporarily unfitted for work, as well as for the support of those who may be dependent upon him in the event of his death. To this end benevolent associations of a permanent and well-guarded kind should be more generally organized and entered into. Each member while employed and in the enjoyment of health, should contribute a certain amount of his earnings to a general fund, to be administered by such association, and upon which he can draw when sickness or adversity overtakes him. They have societies of this kind already at a few of the principal mining centers, but they should be much more general than they are now, that the working miners are likely to become a large and permanent class in this country.

THE Reno *Gazette* thinks the Nevada State Senate lacks backbone because it refuses to take hold of the hill making the actions of hired fighters in the mines a felony. It thinks the bill should be passed.

GEOLOGISTS having reported that there is in Japan enough workable coal to produce a yearly yield, equal to that in Great Britain 1,000 years, the Japanese government have agreed to grant a loan of $1,500,000 for the purpose of working them.

MARSHAL MCMAHON has resigned.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

Investigate and Stop the Loss.

Editors Press:—The following letter has heen received hy me from Yreka, Siskiyou county, Cal.:

"I am more and more convinced that it is utterly impossible to save more than a small proportion of the gold contained in the ores of California, hy what is known as the wet process. The result of my own observation and experience goes to show me that your oft-repeated expression that, of every $100 in the ores of California, hut $40 at most is saved, and that $60 goes down the creek is also too true; and 'pity 'tis, 'tis true,' for it is impoverishing our mines and disheartening our miners, and the more I reflect npon the subject, the more I am convinced that the battery, as usually worked, is at hest extremely wasteful, and at most, unsatisfactory in its result. I have in my mind's eye, at present writing, the result of a company, who worked a numher of tons of ore in an arastra, realizing $24 per ton, which all will admit was good.

"But in this fast age the arastra was too slow, so a five-stamp mill was erected, run up to a high speed, from 7 to 10 tons per 24 hours rushed through the hattery, doing a land-office husiness—company in high feather—result of clean-up, $5 a ton! Further result, an assessment to pay indehtedness and mill shut down.

"Some four weeks since, I run 47 tons through a mill, and I hrought all my skill and experience of 27 years to hear on it; yield, $15 per ton, while the result, by arastra, on same ore, was $50 per ton. The ore actually carried $60 per ton. I mention the foregoing as illustrations of the truth of the conclusions I have arrived at, viz.: That it is sheer folly to expect that the finer gold, which is indeed the larger proportion of the gold contained in the ores of California, can possibly he saved by the rush of water necessary to carry off the pulp."

The foregoing is one of many letters I rceive of tbe same import. The writer is one of the oldest and most intelligent quartz miners of this State, and, as you see, an investigator. Now, when I read so many letters, detailing similar results, take my own experience aud look backward over the quartz-mining districts and sce the losses, I am prepared to denounce the stamp hattery, copper plate and blanket system of mining, when it comes to properly utilizing our wealth and giving a just reward for capital and enterprise, as a dead failure.

Success is the exception, failure the rule. Through recklessness or ignorance, and it matters not which, the result is the same. There seems to he hut one idea when men engage in quartz mining, and this is to simply crush rock. Proper devices and careful handling for saving the metal is merely a secondary matter, when it should he the first. The argument is, gold, heing a metal, it necessarily goes to thc bottom, without any consideration of the laws of resistance; but, as experience shows, this way of mining carries the hands of operators too often into their pockcts to foot the hill of losses, hecause crushing rock don't pay.

Statistics of California quartz mining show that 75%, at least, of all the quartz mills erected in this State are failures, while the remaining 25% bas, through extraordinary richness of the ore, heen profitahle enough to keep the husiness alive, and these successful companies should have heen more so hy better working.

More than half the failures would have hecn successes if they had saved 80% of the value of the ore. The idea that it is only necessary to get a set of stamps, hohhing up and down at a lively rate, to crush rock, then to stand hy and look at them wash the sands (and gold) off, should he stoppcd. A law prohibiting this waste of so precious a metal as gold would more than double our yield, and hy so doing more than douhle the mining enterprises. No mine or mill should he allowed to he worked without having a return of 80% of the value of the ore. This rude way of treating our gold ores helongs to an age when science and machinery were not so far advanced as they are at this time. Silver mining is so far ahead of our universal system of gold mining, in the percentage of metal saved, that one, if he did not know it, would not helieve that the working was in the same age.

It is surprising how few gold miners really comprehend, or seek to know, the waste of their hattery working hy this rushing and crushing system—well named, as it crushes rock, fortunes, and spirits at the same time. And how little they desire to improve upon it. I have frequently asserted, and it cannot he done too often, that the average of California quartz mills do not save 33% of the value of the ores worked.

"But," says one, "I save more than tbat; mine is 'free gold.'" Suppose it is "free gold," and so fine that it swims, is it going to resist a stream of water used to wash the coarse sands off? Not at all. It moves on for miles, and it would seem that quartz men would some day come to their senses on this point.

I may he eousidered as on the war-path against our wasteful system, and I intend to he until a more careful one is entered upon. In so doing, I am going to create investigation, as no miner desires to willfully waste his wealth; and this alone will be worth millions yearly to the people of this State. I have several othcr letters, which are of general interest, that I propose answering through the Press; hoping they will he received in the spirit they are given—for our general good. Almarin B. Paul.

San Francisco, January, 1879.

[The foregoing letters in regard to dry crushing are forcible enough, and they sufficiently explain themselves. We will venture the suggestion that, in addition to the argument, carefully prepared details of comparative working, with the figures, would be likely to receive all the attention that the subject deserves from intelligent engineers.—Eds. Press.]

Traction Engine for Plowing.

Editors Press:—In your issue of the 4th inst., "C. W. M.," alludes to using the Doane traction engine for plowing, in a way that leaves room for a discussion, or calls for practical test. As I have made myself somewhat familiar with the subject, the following few hints may he interesting.

In the first place, it can never be practical to use more than three 12-inch plows, because more will rcquire an engine so large and heavy, that it will mire down when the grouud would he in a fit condition to plow. I thiuk tbat if an engine and boiler could he made out of steel that would not weigh more than 2,500 pounds, and run night and day, as it well could he hy using a headlight, that it might he constructed so that one man could work it.

With such an engine, I see no reason why 40 acres could not he plowed in 24 hours, as the speed might he increased to two or three times as fast as horses now travel, and still do good work.

It now costs farmers $5 an acre to plow, sow and harrow, hecause they have to feed their horses so long without work, all of which might be accomplished hy going over the ground once with an engine. Besides it could he used on a threshing machine, steam hay press, or to haul the produce off the farm. A Subscriber.

Orland, Colusa Co.

Cosmic Meteorology.—No 2.

[Written for the Press by Samuel Purnell.]

In 1867 Mr. Baxendell puhlished the results of a scrutiny of the solar radiation registers at Oxford, England, from 1856 to 1864, aud came to the following conclusions, among others: 1st. That the caloriiic intensity of the sun's light is suhject to periodical changes, the maxima and minima of which, correspond respectively with those of sun-spot frequeucy.

2. That it seems prohahle that the heating rays of the sun consist of two kinds, differing in intensity and suhject to periodical changes, the times of maxima of one kind and those of minima of the other corresponding respectively to the times of maximum frequency of spots. He also pointed out a connection between the mean monthly variations of solar radiation in cloudless days, and the mean monthly range of the magnotometer. In 1871 he published further researches on the changes in the distrihutiou of barometric pressure, temperature, and rainfall, under different winds during a period of solar-spot frequency. He found that changes had taken place in the three elements under discussion which corresponded very closely in their times of maxima and minima with those of sun-spot frequency.

In 1875, Mr. H. T. Blanford, of India, stated, that, from experiments conducted in Bengal, "the result is to me very striking, and if not absolutely conclusive as to the direct variation of the sun's heat with the number of spots and prominences, certainly, as far as it goes, strongly confirms Baxendell's conclusions."

In 1875, Profs. Stewart and Roscoe came to the conclusion that there is more sunshine in London in years of maximum than in years of minimum disturhance. In 1876, Prof. Stewart found that the winter temperature range at Kew, apparently depends on the sun-spot period, heing greatest at times of greatest solar movement, and *vice versa*. In 1877, he produced evidence to the effect that the mean daily range of temperature depended, among other influences, upon the state of the sun's surface with regard to spots. In 1870, Prof. Piazzi Smith, as the result of observations made in Scotland from 1837 to 1869, concluded that a great heat-wave occurs every 11 years and a fraction; its maximum slightly lagging hehind the minimum of the sun-spot cycle. In 1871, Mr. E. J. Stone, from an examination of the records at the Cape of Good Hope for 30 years, stated that thc temperature and sun-spot curves present an agreement so close as to compel him to helieve that the same cause which leads to a decrease of meau annual temperature, leads equally to a display of solar spots. Here also was found the maximum heat slightly lagging behind the minimum spots. In 1873, Signor Celoria observed a marked coincidence hetween the temperature at Milan and the sun-spot periods. In 1873, Dr. W. Koppen puhlished the results of a long series of observations on these cycles. From 1816 to 1854, he states that "the coincidence of temperature changes with the sun-spots does not merely extend over the average length of the cycles, hut reflects all the leading disturhances and peculiarities of the sun-spot periods." He considers that there can he no question of the actuality of the coincidences.

The regularity and magnitude of the undulations of the temperature curves are most strongly marked in the tropics, and decrease toward the poles.

3. As to

Wind Disturbances,

The evidence is very uniform. The frequency of such disturhances at times of most sun-spots has heen obscrved in the tropics, where such disturhances are more marked than elsewhere. Dr. Meldrum, of Mauritius, some years ago estahlished the relation of sun-spots and cyclones in the Indian ocean; and he maintains that the whole question of cyclones is one of solar activity, and that if we write down in one eolumn the numher of cyclones in any given year, and in another the numher of sun-spots, there will he a strict relationship hetween them: "Many sun-spots, many hurricanes; few sun-spots, few hurricanes." In 1873, M. Poey conducted similar researches on the hurricaucs of the West Indies, and found the common periodicity strongly marked. In 1877, it was found that the marine casualties disclosed a cycle closely corresponding with the sun-spot period. The percentage of casualties to the registered vessels of England was 17½% greater during the maximum two years in the common cycle than during the minimum two years, in a douhle cycle from 1855 to 1876, inclusive. The percentage of tropical cyclones during the past two years has not yet heen ascertaiued, but that it will be low is evidenced from the fact that few accounts of such disturhauces have been puhlished, and ships have, for the most part, sailed through tranquil seas. According to the theory under discussion this should be the case, as the present year is one of an extreme minimum of sun-spots, and the probable close of the current cycle.

4th.—Rainfall.

On account of its iudustrial uecessities, and in view of the recurrence of periodical famines of certain countries, the relation of sun-spots to rainfall has been much studied of late years, and many interesting facts have heeu gathered. As this series of articles is principally intended for the disenssion of the rainfall of the Pacific coast of the United States, and its relation to the sun-spots fluctuations, more room will be given to it than to the othcr hranches of the suhject. Messrs. Lockyer and Hunter have again presented a summary of the literature in this direction, which, as far as it goes and is relevant, will he freely used without further acknowledgment.

Dr. Meldrum, from a comparison of the rainfall returns of Mauritius, Adelaide aud Brishane, concluded that evidence of the connection hetween maxima and minima periods and the corresponding sun-spot periods, although not absolute, was very striking. In 1873, Gustav Wex made an examination of the depths of water reported in the Elhe, Rhine, Oder, Dannhe and Vistula rivers, and concluded that the years in which the maximum amount of water flowed down the rivers were those of maximum sun-spots, whilc the minimum amount of water occurred during years of minimum sun-spots.

Mr. G. M. Dawson in 1874, stated that the correspondence between the maxima and minima in the solar-spot cycle, and the hight of the great lakes of North America, though not absolute, was sufficiently close to open up a new field of inquiry. From his investigations, it appeared that, from 1855 to 1868, during maximum sun-spot periods, the lakes were on the average, 14 inches higher than during minimum periods. In 1874, Mr. J. H. Hennessey, from an examination of the rainfall of one of the districts of India, arrived at the conclusion that there is a close connection hetween sun-spots and rainfall. In 1874, Dr. Broun, in an analysis of the returns from ten stations, considered it prohable that a difference of two inches in the rainfall might he expected hetween years of greatest and years of least sun-spot area. Prof. John Brockleshy in the *American Journal of Science*, stated that the results of his examination pointed to a connection between the variations in the sun-spot area and the rainfall; the rainfall rising ahove the mean, when the sun-spot area is in excess, and falling below the mean, iu periods of few spots. In 1877, Lockyer and Hunter puhlished their investigations into the whole suhject, and adduced many new facts, principally with respect to the

Rainfall of India.

At Madras, they found that in five out of six years of minimum sun-spots, during the course of 64 years of ohservation, the rainfall fell short of the average supply, and this exception was in 1843, which was due to a sporadic rain storm in May, before the heginning of the southwest monsoon; and that the average rainfall at Madras, is 40½% greater in years of many than in those of few sun-spots. The rainfall cycle of 11 years at Madras, coincides with the cycle of sun-spots. No numerical proportion has yet been found, either in India or elsewhere, hetween the numher of inches of monthly or annual raiufall, and the actual numher or area of sun-spots.

The expressions heretofore used with respect to Madras may he applied, *mutatis mutandis*, to Bombay also.

In 1810, 1823, 1832, 1852, 1865, 1876 and 1877, there was in India a deficient rainfall, and in the succeeding years there were famines; six of these years fell within the three-years group of minimum sun-spots.

The periodicity in the rainfall at the

Cape of Good Hope

is even more strongly disclosed than in that of Madras and Bomhay. Messrs. Lockyer and Hunter, in summing up, find "ahsolute proof of an 11-years cycle in the great factors of tropical rainfall; and we further find that the 11-years cycle in the separate classes of terrestrial phenomena correspond with the 11-years cycle of sun-spots. We helieve that the supposed inconsistency of the rainfall is simply a measure, not of its freedom from law, hut of our ignorance."

Some curious

Deviations

From this new-found law have heen noted, especially in California, which will he considered further on. The winter rainfall of Calcutta and of Sydney, from 1840 to 1876, shows its maximum during the years of fewest sun-spots; and the minimum winter rainfall is shown during the years of most sun-spots; which is the reverse of what ohtains as regards the rainfall for tho whole year, which coincides with the sun-spot curve. The rain records of Jerusalem, which receives its total annual supply of rain during the winter months, have heen found to coincide with those of Calcutta and Sydney in exhibitiug the greatest amount of rain during periods of fewest sun-spots.

Mr. E. D. Archihald claims that his researches upon the rainfall of northern India point to the following facts: In years of maximum sun-spots the summer rainfall is ahove and the winter rainfall helow the average; while in years of minimum sun-spots the summer rainfall is helow and the winter rainfall ahove the average—thus varying inversely as the spots. (*Nature*, Vol. 16).

Mr. O. A. Derhy says that the relatiou hetween sun-spots and rainfall holds good in the intertropical portions of

Brazil;

The mean annual rainfall varyiug from 10.32 in the minimum to 13.55 in the maximum years. The northern provinces of Brazil in 1877 (a year in the minimum group) experienced the most terrible drouth ever known there; and many drouths have formerly occurred during minimum years, and floods in maximum years. (*Nature*, Vol. 18).

Dr. Meldrum has recently shown (*Nature*, Vol. 18) that the raiufall

At Edinburg

From 1824 to 1872 shows a remarkahle coincidence with the sun-spot variations; he finds that at Ediuburg the year of minimum rainfall was on the average the year hefore the minimum sun-spot year, and that the year of maximum sun-spots coincided with the year of maximum rainfall. The rainfall at Paris from 1824 to 1872 also increased and diminished with the sun-spots, the fall heing greatest in the years of maximum spots. The minimum rainfall occurred on the average in the year immediately preceding the year of fewest sun-spots. Dr. Meldrum remarks that the rainfall tahles of Edinhurg and Paris, especially those of Edinhurg, are more favorable to the theory than are even those of Madras. He remarks, further, that the rainfall of 54 stations in Great Britain from 1824 to 1867 was .75 of an inch helow the mean when the sun-spots were helow their mean, and .90 of an inch ahove it when the sun-spots were in excess; and for the corresponding years from 34 stations in America from 1824 to 1867 was .94 of an inch helow, and 1.13 inches ahove.

The very ingenious method hy which Dr. Meldrum arrives at this result I would he glad to apply to the rainfall tables of California, were it not that the principle when fully carried out demands a continuous record of some 50 ycars, and our local tahles not heing even 30 years old a harmonic mean cannot he accurately ohtained; still, a tahle made upon this principle will be found further on.

Without going further at present into the literature of the vexed question of the relation of sun-spots and rainfall, it may now he more profitahle to examine briefly the connection between the spots and

Other Terrestrial

And even celestial motions and phenomena.

Mr. F. Chamhers, of Bomhay, (*Nature*, Vol. 18) considers that the Bomhay harometric observations afford fairly conclusive evidence in favor of the sun heing hottest ahout the time of maximum sun-spot area, and coolest when the spot area is at its minimum. The hest place to ohserve this is in Central Asia, where the annnal variation of the harometric pressure is greater than in any other portion of the globe. The harometric curve lags hehind the inverted sun-spot curve, particularly in the years of maximum sun-spots. Upon the whole there is in India a low pressure ahout the time of average sun-spot maximum, and a high pressure ahout the time of sun-spot minimum.

The parallelism hetween the sun-spot curve and that of the displays of the aurora polaris from 1780 to 1870, was shown hy Prof. Loomis in a striking and convincing manner, and is quoted by Prof. Stewart (*Nature*, Vol. 16,) with approval. In this, the two curves are seen to follow each other closely; many sun-spots, many auroras; few sun-spots, few auroras.

Dr. Fritz, of Zurich, has shown that, in Eu-

Continued on page 70.

Mechanical Progress.

Recent Improvements in Plows.

The improved American plow holds a high rank among the implements of modern husbandry, not only at heme, but in the foreign market. In form, materials and construction it appears to be all that it is capable of being, and yet there are constant developments of new points of excellence. The most obvious improvement within the last few years consists in the use of hard metal, first for the edge, and later for the entire wearing surface. Chilling the edges and point of the share and the bottom of the land-side were the first steps in the line of progress, made about 30 years ago, but within the last 10 years attention has been directed to the importance of reducing the friction of the mold-board. Hardened steel was introduced for this purpose, and is still recognized as the best material where soil is wholly free from grit, but it was found that a chilled surface of cast-iron, in combination with the chilled share and land-side, was more easily kept in repair in all soils containing grit. The well-known process of chilling first resorted to, consisted in running the molten metal against the surface of cold iron. This method, while rendering the metal harder, made it correspondingly brittle, and required great care in the mixture of the iron to make the chill penetrate uniformly. This plan also required a method of annealing, sometimes with hot water, or by building fires on the back of the mold-board, and sometimes by covering with heated sand.

Later improvements in mixing metal have been successfully made, so as to secure entire hardness throughout, without the chilling process. Plows made in this way are usually known by appropriate names, such as "Carbon," "Diamond," "Adamant," etc. Long experience has taught that steel in certain combinations will mix with melted pig iron, and with the addition of certain chemicals will make a homogeneous metal by pouring it into molds at the right time, which time is ascertained by means of its color. In this way the result is "hardness, uniformity and strength."

In former years, plows made of cast iron were so rough that farmers were severely tried in keeping them bright. As plows have grown harder the polish is more difficult to produce, as well as more durable, and on the metal here referred to, is said to suffer little from corrosion. As the friction of the plow is equal to about 35% of the whole force of the draft, every expedient to reduce it is important to the plowman, while every increase of labor is at the cost of some useless expenditure.

A still better improvement in this direction was recently achieved by the introduction of a reversible point in the share, which thus becomes self-sharpening, and enables the farmer to keep the bottom of the plow level, thereby avoiding the friction that arises from a projection of the point of the share below the general level. It has been found that the effect of a sharp point is to sharpen the wing also. Among other improvements by various manufacturers, is the setting of the beam in the center instead of one side of the line of resistance, which is adjustable at the standard so as to produce a balance, avoiding side drafts.

Joining Lead Pipes Without Fire.

In connection with many industrial processes it is desirable to join lead tubing where the use of fire would be practically inadmissible, and to meet these cases an ingenious method has been proposed by Mr. A. L. Bricknell, of Southamptou Buildings, by which he can make a thoroughly reliable and well-shaped joint quickly and cheaply without the use of fire, solder, couplers, or other dangerous or costly materials. To do this he first drives a hard wood or metal plug into the bore of each pipo sufficiently large to admit about one-half on its outer surface. The enlarged lead pipe is hammered up a little to compensate for the reduction of thickness by enlargement, and the ende to be joined are rasped or scraped clean and bright on their faces. The tube is then inserted abent half way into each of them, and by snitable mechanical appliances they are pressed into contact until they are welded together, being united by cohesion, and forming a continuons homogeneons pipe.

The mechanical appliance which he prefers to use consists of the two halves of an outer die, held together by two longitudinal horizontal connecting bolts, on each side, and an inner die, also divided vertically into two halves on a line, which would pass through two power bolts. The outer and inner dies, with the two connecting and two power bolts, and their respective nuts, constitute the press. Power applied to nuts working on the power screws forces the inner die downward upon the thickened end of the lead pipes, and effects the operation of cold welding by pressure, as will be readily understood. The nuts are most conveniently turned, particularly in confined spaces, by ratchet wrenches, which hold in vertical grooves or notches provided around the nuts for that purpose; and, as the power bolts are cut with right and left hand threads reepectively, the wrenches react upon each other, which dispenses with the necessity for holding the press, and saves the lead pipe from tereional etrain. When the joint has been welded, the dies being in halves, are easily removed. The particular office of the tube is to resist the inward yielding of the lead to the force exerted outwardly upon it by the press, and thus compel the lead to receive a much greater pressure than it could otherwise possibly sustain. The grooves or projections on the tube materially aid this result by retarding the escape of the lead from the flanged part of the joint, longitudinally between the tube and the press. The use of the tube, which has the same internal diameter as the pipe, also maintains a full and undiminished here or waterway.

For the purpose of joining lead pipes at an angle to others he casts short and compact T or other suitably shaped junction or branch pipes of lead, and proceeds, as before explained, except that ae such pipes may be cast with enlarged and thickened ends it is not necessary to prepare them by enlarging and thickening, as in the case of ordinary lead pipes. These lead castings may be conveniently made in small iron molds fitted with iron cores, which can easily be removed. Such molds may be arranged to receive the ends of taps and such like fittings, which may thus be cast into the lead junction pipes. In some cases a small ring or short piece of lead pipe may be cast around a fitting at a distance from its end sufficient to allow of its projecting into a lead pipe far enough to form a substitute or equivalent for the internal tube. When this is done the part of the fittings so projected must be grooved to imitate the tube it represents. If a fitting is previously tinned at the part upon which it is intended to cast the lead the latter becomes most firmly attached to the fitting, and when welded to a lead pipe, as described, an extremely solid and reliable combination is the result. A final stop or end to a pipe may be a flanged cap or socket of lead welded on the end of a pipe over the interior tube, in a like manner as two pipes are joined. It will of course be understood that this is only intended to explain the general principle of Mr. Bricknell's invention, for it will be apparent that other devices may be used for compressing the pipes end to end, and that cams, wedges, or other means, may be substituted for the power screws for drawing the two parts of the dies together. Mr. Bricknell's invention is likely to come largely into use, and is certainly most rapid and cleanly.—*London Mining Journal.*

The Wheeler Process for Welding Iron and Steel.

The principle of the iuvention ie to bring the two metals simultaneously to a welding heat in one pile, and then manipulating it. The one important provision—the key of the situation, so to speak—is to effect while in the furnace, and immediately afterward, a practical exclusion of oxygen from the surfaces of steel intended to be welded. This is done by boxing or inclosing the steel with plates of iron, which plates, made to lie in overlapping contact at the corners of the pile and with its end plates, are found to effect a satisfactory exclusion of oxygenating atmosphere. Such a pile, heated gradually so as to permit the snitable penetration of the heat through its mass, bringing the steel into a condition of semi-fusion, is given at last a wash heat, to bring the iron casing to a proper welding temperature, when the whole pile—that is, the box with its contents—is passed through the rolls. After one or more passes, the welding of the iron to the inclosed steel will be attained effectually, and the eteel, when of more than one piece, will be welded into a homogeneous mass.

This process is simply a method of welding, a process which offers for our consideration nothing in any way anomalous, and is one, the laws of which are found, upon examination, to harmonize with those of other metallurgical processes commonly practiced. It has been the practice for a long time to transform quantities of eteel scrap into homogeneous masses by melting it in refractory crucibles, which are kept as such, and which in use are covered to exclude the atmosphere; while in the Wheeler process a malleable crucible is used, which is fed to the rolls of the mill, and the material of which is united to its contents and becomes part of the product. The contents of the crucible are not necessarily melted, as completely in the new practice as in the old, but they are brought sufficiently near to the melting point, to secure homegeniety of product.

Phosphorus in Railroad Iron.—Mr. Alfred Earnshaw, of Philadelphia, contributes to the *Bulletin* of the American Iron and Steel Association an article on the true test of steel rails, which is of considerable interest. Referring to the reported falling off in quality in rails produced in recent years, he states that phosphorus has by general consent been elected the cause, hnt does not know that it has been shown or ever will be shown that a rail with say 0 15% of phosphorus will not wear as well as one with 0.075%, as long as it is well made and contains its due proportion of carben and manganese. The tests made by the railroad companies should be physical tests, such as might be made by Thurston's machine, and the chemical tests should be made by the steel manufacturers. It is obviously no business of the railroads what per cent of phosphorous a rail may contain provided it fulfills the requirements of the physical tests and gives satisfaction in the track, and the steelmaker must be allowed to work out for himself the commercial as well as the chemical problem of how to make cheap rails that will wear most satisfactorily.

Scientific Progress.

Are the Elements Compound Bodies?

Prof. Lockyer's recent announcement to the French Academy of Sciences, that he had discovered that a number of bodies, hitherto considered elements, are really compound bodies, is still exciting much interest everywhere. Since the publications above alluded to, the Professor has read a paper in relation to his investigations, before a very full meeting of the Royal Society of London, which is replete with the most interesting physical facts, but the conclusions and inferences of which, are considered by chemists, as somewhat over sanguine. We condense from a brief summary of this paper by a contemporary, as follows:

His experiments and researches bear upon the subject in two directions. He has examined solar and stellar spectra, and mapped the lines which he has compared to the spectra of what he believed to be pure elements. He finds his results confused by the continued coincidence of numerous lines belonging, presumably, to different elements. Many of these he has found it possible to eliminate by carefully purifying the metals experimented upon; others have remained. But prominent chemists, including Roscee, Frankland, Williamson, in the discussion following the reading of Prof. Lockyer's papers, seemed to believe that the difficulty of eliminating impurities was so great, and the spectroscope so sensitive, that the basis of his direct experiments—the purity of the elements used—was unsound.

Prof. Lockyer, however, claims to possess means for detecting impurities and for distinguishing them from constituents. By former experiments with the spectra, of alloys containing different proportions of two metals, he proved that if one constituent was present in very small quantity, only the lines longest in the spectrum of the pure specimen appeared, while the others came into view only when the amounts in the alloy increased. He argues from this that when the longest line of an element is absent, the body examined is free from it.

His experience with alloys was extended to compound bodies, and here he discovered most remarkable facts. He found that the spectrum of such a compound as chloride of lime, taken at a low temperature, differed from that of calcium; but that when the temperature was increased the spectrum gradually changed, and finally the lines of calcium appeared—a fact which he attributes to decomposition of the compound. Noticing, then, that a further increase of temperature, instead of leaving the spectrum of this so-called element unchanged, causes it to alter continuously as the temperature rises, he argues from analogy, that calcium itself must be decomposable, and, therefore, cannot be a true element.

The examination of the changes in the spectra of elements, he has extended to four—calcium, iron, lithium and hydrogen—from the range of temperature of a Bunsen lamp, to that of the sun, or Sirius, which, being the brightest, is probably the hottest star. Thus, at the temperature of the electric arc, the calcium line in the blue is of great intensity, the violet H and K lines, being still thin; in the sun the H and K lines are very thick, and the line in the blue is thinner and less intense than at the temperature of the electric arc. In the spectrum of the star *a*, Aquilæ, the K line is only half as wide as the line H, while in the spectrum of *a*, Lyræ, and Sirius, only the H line of calcium can be detected. The hotter the star the simpler the spectrum. Mr. Lockyer's experiments with the elements have extended through a period of four years, during which time 2,000 photographs of spectra have been taken, and more than 100,000 eye observations have been made.

That the facts proved by Prof. Lockyer, of a variation of the spectrum of some elements in connection with variation of temperature, experimentally and by the examination of stellar spectra, are highly important, cannot be doubted, and it will be acknowledged that they point strongly to the conclusions which he has drawn from them; but the direct proof submitted in regard to the coincidence of the lines belonging to different elements, as found by the mapping of spectra of pure metallic elements, will not be accepted until sufficient and unimpeachable evidence is brought of the purity of the material experimented with.

The extreme sensitiveness of the spectroscope, going, in many cases, far beyond the means of eeparation at the disposal of chemists, will make the latter cautious in their acceptance of such spectroscopic results. As an instance of this sensitiveness, Dr. Frankland mentioned in the discussion that a trace of copper not exceeding one fifty-millionth part of a grain had given copper lines quite vividly, although only for an instant, while four one-thousandths of a grain had been sufficient to give copper lines continuously for over six houre.

We need hardly add that if Prof. Lockyer does furnish final unimpeachable proofs, chemists have not advanced one step in devising means for carrying into execution the dissociation of elements or transmutation of metals, beyond the knowledge that it will require intense temperature.

The Heating Power of Hydrogen.

As the result of enquiries I have made, and experiments I have witnessed, in the process of making gas from superheated steam and petroleum, in which the superheated steam is made to give up its oxygen during its passage through red-hot iron tubes and then through coke and iron scraps, thus producing hydrogen gas, subsequently combined with petroleum to give it illuminating power, I have ascertained that the cost of the hydrogen is not more than about four pence per 1,000 feet. It occurs to me that this fact can be utilized in the reduction of metals by employing the hydrogen thus produced as a heating power in furnaces constructed to admit of such use. If consumed as fast as it is made, the danger from storing it would be avoided. Forty years ago I had a narrow escape for my life while experimenting with this gas, and retain a respectful admiration of its power. One ton of coal will now raise as much steam as 60 years ago it took 10 tons to produce, the gain being due to the more scientific employment of the fuel; but the waste of heat is still so great that its utilization is a matter of world-wide importance. In no process is the waste so enormous as in the reduction of metals, especially of the precious metals, producing great losses by excessive volatilization and the mechanical dispersion of the finer particles. I have long thought that defects of this character could be avoided; and when Mr. Probert first went out for the Richmond company I asked his especial attention to the subject of improving the furnaces, which at that time were distributing metallic dust rich in gold all around the works; he has reduced this loss to a great extent, but I believe there is still great room for improvement, and I think it will be in the direction of supplying the oxygen necessary, by other means than the blast of air, and by the use of hydrogen as the chief heating medium.—*Cor. London Mining Journal.*

Proposed Material for Standard Weights.

It is proposed by Herr F. Mohr in the *Annalen der Chemie* that glass containing a large portion of silica shall be employed as the material for weights and measures. He remarks that the only men of science who work with good balances and accurate weights are the chemists; and yet, hitherto, none, even of that class, has considered it necessary in his weighing operations to consult the barometer and the thermometer, except as regards the gases. In one and the same set of weights are to be found pieces of brass or of platinum, and the same weights are used in Munich, at the hight of 1,700 feet, and in London, at slight elevations above the sea level. Against the consequences of these fallacies the best weights are no protection, and we may say that this source of error has been neglected in all chemical discoveries. We must easily see that it is unjustifiable to weigh finer than to milligrammes in all cases where a platinum crucible is concerned, or the ash of a filter, or glass vessels holding a considerable volume of air, or precipitates not absolutely insoluble. Rarely is the substance weighed which we are in search of, as silica or alumina, but it is generally calculated from some compound, and this introduces the further uncertainty of the atomic weights which are brought to a round number, as in case of phosphorus, sodium, calcium, magnesium, etc. It may be said that the whole structure of organic chemistry has been erected with a false atomic weight from carbon, which is even yet uncertain. A fall of the barometer of 10 mm., which may occur in one day, will render a kilo. weight of rock crystal lighter by 5.3 m. grammes. What is the use, therefore, of adjusting a standard kilo. to the decimal of a milligramme if the haromcter and the thermometer can bring about such changes? Weights of cystal and of platinum are not commensurable unless the atmespheric pressure is taken into account.

To Indicate Dangerous Accumulations of Fire Damp.—One of the most interesting attempts to indicate dangerous accumulations of fire damp is an apparatus devised by a Frenchman, J. Cequillion, which he calls a *grisoumeter*, the action of which is based upon the decomposition of hydrocarbens by a red-hot palladium wire, in presence of steam. This reaction he used for the analysis of the air of a mine. He has now found that he can replace the palladium by platinum, by the use of which the disadvantage that the Plante pile cannot be employed, is overcome. Recent researches of M. Coquillion have shown that the bicarbide of hydrogen detonates more violently than the monocarbide, that palladium produces a smaller detonation than the platinum, and that both metals can burn small quantities of gas. M. Coquillion has accordingly replaced the former by the latter metal in his portable apparatus.

Conductivity of Heat.—Some recent investigations concerning the coefficient of conduction for heat of various building materials, excluding the influence of radiation, and making measurements by means of the thermo-electric multiplier, show that stones are much better conductors of heat when wet than when dry, and that various classes of them, such as marble, sandstone, granite, etc., have approximately the same coefficients of conduction, while dry bricks of all kinds are much worse conductors than the natural stones.

Mining Share Market.

Ths mining share market during the past week has been devoid of general interest. No strong feature has been developed, nor has any movement calling for special comment occurred. A dearth of orders from what are snpposed to be the controlling powers, suppressed all enthusiasm, and lead outsiders to realize freely when opportunity offered. As a consequence, transactions were comparatively few and limited, and prices held to a low range. The hope of early developments on the Comstock belt serves to keep alive confidence, but fails to enthuse the street. The prospect sustains the market, but gives it no positive strength. With life so kept in it, only a little in the way of new ore finds would be required to render the market buoyant, and perhaps "booming." Until then it will probably remain fitful and spiritless, fluctuating only over a narrow margin. The long impending conflict between Mr. Sutro and the Comstock companies seems about to be precipitated. New issues and complications have lately arisen between these parties, which will now, most likely, have to be settled in the courts.

Bullion Shipments.

Since our last issue shipments of bullion have been as follows: Tybo Con., Jan. 17th, $4,064.60; Argenta, Jan. 19th, $5,847.38; Tybo Con., Jan. 20th, $4,087.41; Christy, Jan. 26th, $7,327; Con. Virginia, Jan. 25th, $17,793.53; Trojan, Jan. 22d, $6,860.48; Alexander, Jan. 27th, $6,163; Tybo Con., Jan. 23d, $3,986.99; Tybo Con., Jan. 24th, $3,923.55; California, Jan. 25th, $101,797.54; Bodie, Jan. 22d, $11,414.37; Standard, Jan, 23d, $17,985.53; Northern Belle, Jan. 22d, $2,631.69; Trojan, Jan. 22d, $6,880.30; Paradise Valley, Jan. 23d, $3,334; Paradise Valley, Jan. 24th, $3,315.78; Grand Prize, Jan. 27th, $21,000; Ophir, Jan. 24th, $24,030.96.

Leaching at the Silver Peak Mine.—The shipment of bullion from the Silver Peak mine, Esmeralda county, Nevada, for 1878, was $112,417.63. Of this, $21,106.90 was from the old amalgamating work's mill to April 3d. The remainder, $91,310.73, was from the new chloride leachiug mill, six and a half months' run. These works are under the superintendence of Mr. D. W. Bruntou, who has introduced an improved and extremely simple system of leaching. Hs is also nsing an improved form of fnrnace which has been very successful, and for which he has applied for Letters Patent.

Hymenial.—We acknowledge with pleasure the receipts of cards of invitation to the marriage of Miss Nina Evans, daughter of A. H. Evans, Esq., to Mr. Bartram Zevely, at Washington, D. C. Tbs ceremony was announced for January 30th, at ths Churcb of the Ascension, and has therefore already taken place. Although it be late, we tender our sincere congratulations and good wishes to the happy pair, and in this sentiment our readers and patrons will join, for Mr. Evans, the bride's father, is our agent at the national capital. May they live long and be happy.

Money.—People who can appreciate money, or wbo have learned how to acquire and to bold property, will take interest in Mr. Del Mar's able study, in this issue, of the evolution of ideas and of the words coined to express them, in tbe currencies so intimately related to tbe precious metal mining industry of the world. He shows the rationale of the word-currency of Currency, and the value that is to be attached to Value, leaving the reader to travel on himself over tbe rest of the ground of property *in propria personæ*.

The New Afterthought Mill.—Tbe Afterthought mining company, of North Cow Creek mining district, Shasta county, Cal., are putting up a new 10-stamp mill on ths site of the old one (burned last spring), and expect to havs it running by the 1st of April. The O'Harra process is to be used, which is chloridizing and leacbing. The experience in the old mill was very satisfactory, so they have no doubt it will work tbe ore to their entire satisfaction. They think they can work Meadow Lake or any other ore.

The Kendall Ore Stamp.—Oue of the Kendall ore stamps mills, wbich we recently illustrated in the Press, is running at Rough and Ready, near Grass Valley, and is said to be crushing one ton per day, giving excellent satisfaction. Another is running at Sonora, Tuolumne county, and there are three in Amador county. One has also gons to Caribou.

A cargo of Carrara marble, lost eight years ago at sea, and recently discovered, was found to be completely honey-combed by some marine boring animal.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

A Thrifty Town.—*Ledger*, Jan. 25: Amador City is growing rapidly and business of all kinds is very brisk. Everybody seems busy and money is circulating freely. The Keystone mine moves along in its career of gold production, pay-day comes with clockwork regularity.

Piping.—The work of laying the pipe from the Oneida mill to the head of the Moore mine ditch was commenced last Wednesday.

Struck Ore.—In the shaft of the Tellurium mine a veiu of orc was struck on the 20th inst., very rich in sulphurets and free gold, at about 140 feet in depth. They have had very hard rock for some time past; and have consequently made rather slow progress in sinking. The veiu seems to be widening as they go deeper.

Plymouth.—There is more work going on here than usual. Capitalists are investing their funds in the development of our mines, with the indications strongly pointing to rich returns. Lucky Baldwin, it is said, has bonded Pondstouo's mine in Big canyon for $60,000. Hoisting works are already up, and the mill is under contract, and will be rapidly built. A San Francisco company are also about to rssume work on the Central mine, on wbich work was suspended last year.

Strikes.—They have pushed a tunnel into the Thomas George claim a distance of 130 feet, and are rapidly approaching the maiu ledge, having already passed through several small veins of rich quartz. The surface has been worked for yeara by Mr. George, and has yielded handsomely of the coveted metal. Work on the Enterprise mine will, according to report, be resumed. It is also reported that rich orc has been struck in the new shaft south of the Phœnix—Hooper & Hayward's claim. If it proves true, we shall ere long have another mill turning ont bullion. Two of our pocket miners, Tripp & Smith, stumbled across a rich pocket last week, about four miles uorth of town, and took $10 to the pan. Other parties on the same range are making good wages, so that our placer diggings are uot all played ont. The Phœnix is surrendering quartz of the richest quality. A. Hayward has beeu up, and ordered the Superintendent to buy all the wood he can get, so as to insure ths continuous running of the works. A disbursement of mint-drops—double eagles—is expected this week.

CALAVERAS.

The Gwin Mine.—*Chronicle*, Jan. 25: A cousiderable stream of water was struck in the 1500 level of the Gwin mine tbia week that for a time threatened to delnge things generally. All the pumps and one bucket were kept very busy for several days in preventing the water from filling the mine. We learn, however, that the water has greatly diminished in quantity and that no further trouble is anticipated from that sourcc. A report was also in circulation bere that the 1500 level was gradually closing, but as we have been unable to trace the rumor to any authentic source it is probable that tbe truth has been greatly exaggerated. The hatteries are running as usual with fair results.

Hauling Rock from the Banner.—Another crushing of ore has been mined at the Banner mine, at Glencoe, and the work of hauling it to Garland's mill was commenced last Tuesday morning. There are 100 tons of ors on the dumps, none of it has ever yielded less than a $100 per ton.

Clean-up.—We learn tbat a partial clean-up was made at the Mammoth hydraulic, lately, the yield being great, even in excess of expectations.

New Mill.—A new 10-stamp mill has lately been put on the Garabaldi mine, located about a mile and a half below Robinson's Ferry on the Stanislaus. There is a good deal of activity bcing displayed in mining operations in the southern part of tbe county. The Morgan mine at Carson Hill is being more vigorously worked than ever, and expensive machinery has been put upon the Melones mine at Robinson's Ferry.

EL DORADO.

About Kelsey.—*Mountain Democrat*, Jan. 25: The Estrella mine is sitnated on a lode lying about a half mile east of the Gold Deposit lode, with the Doncaster and Saint Lawrence lode lying between them. All of the lodes are running nearly nortb and south, cutting the formation at an angle of about 20°. They are situated in a belt of country composed of slate and porphyry, which has been fabulously rich in placer gold, and therc is every evidence to lead one to believe that these four lodes are the sources from whicb the vast amount of gold which enriched our ravines and gulches was derived.

INYO.

New Silver Belt.—*Independent*, Jan. 18: Tbere is something of a local excitement regarding discoveries made lately in this vicinity. From the Yellow Grade mines below Cerro Gordo, there evidently extends northward a silver belt whicb includes in the same general liue tbe new mines belonging to Meysan, Hanger, Palmer and others running above Swansea. Old ledges of the same charactsr are known to exist on the mountain's side bslow Hahn's and New York peaks, and still further north above the Eclipse gold miue. Tbis brings us nearly to the south end of a well defined ledge which is traceable for more than a mile in lengtb. The Desaliar party are opening their mine, and have done sufficient to show a remarkably good "prospect," at least. A tunnel 22 feet, running with the ledge and attaining a depth of about 30 feet under the snrface, shows on top and bottom a solid, 18-inch ledge of gray carbonate orc. A specimen of this weighing some 40 pounds and assaying $400 per ton, may be found at Levy's saloon and examined by the curious. A piece of tho same weighing 92 pounds, with stratas running through it assaying from $800 to $1,000 per ton, has been sent to Bodie, and for a time will be exhibited at Cullen & McDermott's saloon. The boys have from 15 to 20 tons of such ore on the dump, and their property, for the present anyway, is not for sale. It lies in an unbroken lime formation, stands at the regulation angle into the hill, the walls being judged perfect by old miners. This ledge is situated about half way up the Inyo mountains across the valley, and some 10 miles distant from Independence. In the old days of San Carlos, Chrysopolis and Bend City operations this country referred to, above the foothill region then worked, was just beginning to be prospected when the Indians made things entirely too hot for continuous and steady work. Since tbeu the valuable mines right before our doors, as it were, have been comparatively unheard of until tbe present.

MONO.

Open Winter thus Far.—Bodie *Standard*, Jan. 25: The continued fine weather of the past week has rendered it possible for mining companies to pursue their workings without interruption, and well have they improved the opportunity. Dump piles have increased in size with remarkable rapidity, and explorations under ground have been pushed ahead with vigor and energy. Such au open winter is one of the things which surprise the oldest and most knowing inhabitant, and is said to be almost unprecedented.

The Mining Outlook.—The most confident people in Bodie are those whose duties render them most familiar with the mines. The knowledge which the reporter obtained in his rounds make him the most sanguine of all in his estimate of ths future of Bodie district. There has never been a time in the history of the camp when there was so little doubt as to its great resources as now. The stock market, which is in a sense the barometer which gauges the estimation in which mining properties are held by the public, exhibited a somewhat stronger tone during last week, the favorites being South Bulwer, Summit and Dudley. In the former we have been called upon to record a strike of the most important character. The Summit mine is and has been a great favorite with investors, and the raise has probably been caused by a general desire to "load up" with that particular stock. The Dudley is running a crosscut at 300 feet depth, of which great hopes are entertained. The stock market, after all, throws but a fitful and uncertain light upon what is really being doue. The dumps which are growing to gigantic proportions about many of our hoisting works are really better monuments of the work which is being accomplished.

Work at the Various Mines.—Mono is about to engage in an exteusive and comprehensive system of prospecting the northern portion of its own ground as well as tbs southern end of the Bodie, in which the Bodie mine will share the expense. The Red Cloud has again resumed operations, and the mine is now free from water for the first time since last August. As the east crosscut was approaching the Red Cloud vein when the water came in, and a west crosscut will at once be started for the Packard and Morton ledge, an early development in that mins is among the prospecta of the early future. The Noonday is looking remarkably well, the ledge having widened very materially since last week. Work in the main shaft of the Con. Pacific is being pushed night and day. The rock in bottom of shaft is quits hard, with streaks and hunches of quartz coming in. The shaft is now down about 200 feet, and everything is working well. In the Standard mine they have an immense amount of ore in sight. Much of tbeir richest ore is left standing, as they can extract it at any time. They can get out all the ore they cau crush while doing work for tbe exploration and development of tbe mine. They have reserves containing orc worth $2,000 per ton. The Bulwer company have over 800 tons of rich ore at the Bodie mill, and will begin crusbing as soon as water can be obtained. Work is going on as usual, except in some of the little outside mines, which are some distance out of town aud have been shut down for the winter. Business men from California are buying lots in the town of Bodie and will open places of business thereon early next spring. In the South Standard good progress has been mads in the east crosscut on the 400 level, having advanced some 70 feet through favorable-looking ledge matter. In the west crosscut, on the same level, progress has been slow, owing to extreme hardness of the rock, which is blue porphyry with occasional seams of clay. The water is not quite so strong; no difficulty is experienced in handling it. Machinery working well.

NAPA.

May Resume.—*Calistogian*, Jan. 23: Tbere is much talk about working soms of tbe many silver claims in the vicinity of Calistoga, and a few people from abroad have lately visited tbis section for the purpose of looking over ths mining district, but whether anything worth mentioning will soon result from such talk and visits remains to be seeu. One thing is certain, however, and it is that tbe question as to whsther the large ledges of silver-bearing ore are really of sufficient extent to guarantee the erection of quartz mills cannot remain unsolved a great many months longer.

Chrome.—H. A. Aldrich and W. W. Eggert, who own a farm near Glenbrook, in Lake county, have discovered an exteusive deposit of chroms iron on their land. They have prospected sufficiently to conviuce themselves tbat thers are thousands of tons, or for aught they know, ths deposit is unlimited. Assays have been made, and tbe owners state that the assayers in each instauce assured them that it was the richest ore of the kind they ever saw. Aldrich and Eggert will probably soon mine and ship a large amount of the ore, as they have an offer for it. A specimen exhibited in town last week looks very fine and appears to be all they claim for it.

NEVADA.

Started Up.—*Transcript*, Jan. 26: The Manzanita gravel claim, situated on the outskirts of the town, has started in for regular business. Although not in full blast yet, owing to the scarcity of water, they are utilizing all the water running in the Snow Mountain ditch, which yesterday amounted to 1,400 inches. Employment is given hers to between 40 and 50 hands.

Other Hydraulic Mines.—Hirschman & Co., near town, will work their property for all it is worth, as soon as ths ditch company can furnish them water. At Chalk Bluff, Hussey's Hayward's and the Bird's-eye Creek companies are making the dirt fly at a lively rate. The Cascade ditch is running a good-sized head of water, and the following claims will be in full blast shortly, some of them having commenced washing already: The Camden and Florence at Hunt'a hill; Jacobs & Sargent at Quaker hill, and Sim Jordan's at Scott'a flat. The North Bloomfield and Milton companies will be grinding out the gold as fast as ever shortly, if thers is not an entirely unexpected clearing up of the weather.

The ditches in the upper part of the county, which have been choked with ice and suow for some time, are now clear and the hydraulic prospect is good.

Vein Mines.—The sngine of the Scadden Flat hoisting works has been driving the pumps steadily all week. The shutting down, caused by the cold weather, lasted bnt a few days. The shaft of the Iron Clad mine below Rough and Ready is dowu 150 feet. The vein is good size and quality, and aa far as prospected has yielded $35 per ton. The Myers Ledge in which a rich strike was reported some time ago, is located near the upper end of Willow valley. The owners are starting an incline preparatory to the erection of hoisting machinery. The mill at the Deadwood mine will start up again next week. New coppers and new concentrators have been put in and other important improvements made. They have about 200 tons of ore on the dump at presnt.

Rich Quartz.—*Foothill Tidings*, Jan. 25: Some exceedingly rich quartz was taken from the Gold Hill mine a few days ago, by tributers, from the second level, 350 feet south of the shaft. The specimens taken out were very heavy in gold, some of the pieces but a few inches in thickness being estimated to contain several hundred dollars. This rock is probably on the line of a pay chute which is to be found in that part of the mine. But it will be several months before this can be tested, as by reason of the late cold wsather cutting off a water supply for the engines (the water from the shaft not being suitable for the purpose), and but a limited amount of wood on hand, the mine has been shut down until the winter season is over. Work will be resumed as early in the spring as it will be possible to obtain a supply of fuel at reasonable rates.

Watt Blue Gravel Mine.—The Superintendant's letter of the 17th inst., says that the main cast drift is in 1,200 fest, and is making fair progress, considering the extrems hard character of large boulders. There is no change in the appearance of the gravel since ths last report. The uorth drift, west of No. 2 wiuze, is in 60 feet, without any change.

SHASTA.

Afterthought.—Reading *Independent*, Jan. 23: At this miue work on the furnace is being rapidly pushed forward. The different parts of the works are being placed in position. The indications now are, owing to the very favorable fall and early winter weather, that ths mill will be completed for running sooner than expected. The fire-proof rock is already prepared for ths bottom of the furnace, and placed in position. The rock, in forming a bed, is claimed to be far superior to brick, not being as liable to be displaced by the plows passing over, and on account of the even and smooth surface there will be no danger of caking or choking up as heretofore by brick beds. The retorting works will be situated in about the same position as before, but with the advantage of a flue which will be constructed to convey away from the retort the smoke, flames, sparks and fumes arising, to one of the chimneys, situated some distance from tbe mill. This will be another great precaution against fire.

Copper City.—As work progresses the prospects here improve. The Extra company make their regular shipments of bullion and in one

[Continued on Page 76.]

Continued from page 66.

rope, the severest hailstorms occur during years of maximum sun-spots.

Dr. Hornstein, of Prague, has discovered a connection of the wind with the period of sun-spots; he shows that in Prague, as in Oxford, the average yearly direction of the wind in the time from fewest to most sun-spots progresses in the direction of from south to west; on the other hand, in the time from maximum to minimum sun-spots, it shows an opposite variation. He further finds that the average wind strength at Prague likewise exhibits a connection with the 11-years period of sun-spots, inasmuch as both phenomena reach their maxima and minima simultaneously. He says these results are based on 240,000 observations.

Dr. Moffat, of England, in discussing ozone observations from 1850 to 1869, found that the maxima and minima amounts of atmospheric ozone occurred in cycles of years which were coincident with the maxima and minima of sun-spots, the amount of ozone in some maximum years being five times the amount in some minimum years.

Investigations show that in Germany the best years for wine occur in times of minimum sun-spots.

Cassini has observed that the zodiacal light is much more brilliant when numerous and large sun-spots are present, and that it diminishes in brightness when sun-spots are few.

Having up to this point indicated some of the related celestial and terrestrial phenomena, it will be proper to inquire more particularly into the

Sun-Spots Themselves,

And endeavor to arrive at some reasonable hypothesis as to the nature of the sun, of its action upon the earth and the atmosphere, of the nature of sun-spots and the probable cause of the same.

The maximum, intermediate, and minimum presentations of sun-spots, and their related earthly phenomena, are not found to occur exactly at a definite period, but there is such a variation in the time of their recurrence that it is necessary to proceed along the line of averages. For facility of examination and comparison, it is usual to group both the maximum and minimum years by threes, and to place the remaining years of the 11-years cycle into the immediate group. The exact year of the minimum period, the year before, and the year after, constitute the minimum group, and the maximum group is formed in an analagous manner. The intermediate group may be called the average of the cycles; and natural motions may, at such periods, be said to be normal. The natural phenomena which seem to be indicated by the sun-spots, and which are, perhaps, produced by the same cause as are the spots, do not always coincide, in point of time or apparent energy, with the increase and decrease of the solar spots, but it has been found that they generally do occur within the three-years group. According to the formula of Dr. Rudolf Wolf, whose period of 11.11 years is usually taken as the average number of years required to form a complete cycle, the mean relative number of sun-spots in the cycle years has been, upon the average, as follows:

1st year	10.8
2d year	10.8
3d year	48.6
4th year	48.6
5th year	83.3
6th year	88.3
7th year	65.3
8th year	65.3
9th year	38.5
10th year	38.5
11th year	10.3

The time of

Average Ascent

Of the period from extreme minimum to extreme maximum, and the reverse motion, are not equal; the former has been found, by Prof. Balfour Stewart, to have a mean of 3.52 years, and the time of descent to have a mean of 7.55 years, giving an average period of 11.07 years. Dr. Wolf, founding his opinion upon a longer series of observations than Prof. Balfour, states that the average time of ascent is 3.7 years, and that the time of descent is 7.4 years, giving an average period of 11.1 or more closely 11.11 years, making nine complete periods in a century. Others, indeed, by basing their opinions on different facts, have estimated the length of the cycle as lying between 10 and 11 years; but Dr. Wolf's investigations have been so profound, so long continued, that, as they embrace the particulars of the sun-spots for several centuries back, his statement is now generally accepted as being true, or nearly so. It will be observed that the time of ascent to maximum disturbance is only one-third of the mean cycle, and that it takes twice as long for the spots to decline to extreme minimum as for the contrary movement. This is both remarkable and mysterious, and, at present, incapable of explanation. Mr. R. A. Proctor, in seeming despair of our ever really knowing much about the sun-spots, recently pronounced the whole subject of the cycle as being mysterious. It will, however, be patiently explored and understood in due time.

[To be Continued.]

A Far-Reaching Echo.—It is said there is a certain point on a ridge high up on Kearsarge mountain where can be heard the rumble of trains on the Southern Pacific railroad as they cross the range to the west of Mohave, 140 miles distant. There is a regular daily train passing at 10:30 o'clock, and upon reaching the place at this hour the noise of the train is heard as stated.

The Evolution of Words and Theory of Value.

[Read by Hon. Alex. Del Mar, before the California Academy of Sciences, San Francisco, December 16th, 1878.]

All words are subject to mutation. They are created, grow, give birth to other words, are altered in significance, absorbed, or lose their force, or dwindle away and become obsolete. This course of change is due to their environment, which is the human mind; and it is, consequently, into the evolution of the intellect that we must look for the evolution of words.

Rude men are rude of speech, and this consists of a few names, which chiefly represent the things of which they stand in present need, as food and drink. The qualities of these things next engage attention, and good, bad, big, little, hard, soft, etc., come into use as words. As the observation of these men extends and their minds develop, so do their vocabularies. Memory carries them into the past, imagination into the future. The single verb, *I am*, finds two new companions, *I was, I will be.* Presently the relations between things, and afterwards those between states of existence, actions and movements, are perceived, and words are coined to express them.

This coinage is usually of old metal, which is cheaper, or easier to obtain, than new. Poor people use their garments for many different purposes, and then often remake them before they cast them off, and buy new ones. The guacho's cloak is also his coverlid; his horse blanket his umbrella, and sometimes even his water pitcher. As it becomes worn, it is cut up for a pair of trousers; and when young Pepe grows old enough to require a similar garb of dignity, it is razeed and rendered serviceable again; and so it continues in use until at last, it is degraded to the menial level of a house-cloth.

It is thus also with words. Among undeveloped and also among decayed nations, the same word is used to convey a variety of meanings, as witness, many of the words in the Choctaw and the Chinese. When social development is taking place, the ever-used word is either specialized, and made to share its original meanings with other special words, or else it is superseded altogether by new terms; in which case the first word becomes degraded, and doomed to extinction. Thus *Lord*, which was once the name only of God, being superseded altogether by the latter term or its equivalent, subsequently became that of any exalted or powerful person; then passed generally to all landed proprietors, and is now attached to every petty boarding-house keeper, in the form of *land-lord. Master*, which had a similar exalted origin, is content to find refuge with the smallest of school boys. *Sire*, in the curtailed form of *sir*, has fallen from the dignity of feudal paramountship to the level of coal-heavers, and dustmen; and like *dame*, another word of noble origin, will probably, in time, become obsolete. In the other case—that is when the old word is retained for a special purpose—its meaning becomes refined with the general refinement of ideas, always supposing, of course, that social development continues. Thus *Barba*, is the Latin for beard, and originally barbarians meant simply a bearded man. *Civitas* is the Latin for a community, and originally a civilized man meant simply a settler or one who dwelt in a community. The difference between *barbarian* and *civilized* was therefore merely the difference between an indigenous Italian and a Roman colonist. The Etruscans, who were a highly refined people, were called *barbarians* by the hand of outlaws and pirates who founded Rome. Little by little these words came to have meanings; then, other words were created to share these meanings, as *wild, untamed, savage*, on the one side, and *enlightened, cultured, refined*, on the other; but the original words were specialized and retained. Passing over the Dark Ages, and observing the word *civilization*, as it came into use again in modern days, we find that it, at first, expressed merely a phase or condition of society; then, according to Guizot, a movement of society, and now it embraces both phase and movement, with the probability that in time, it will be partly displaced by *progress, social evolution*, and other more special terms. The word *money* is due to the temple of *Juno Moneta*, where the coins of the empire were fabricated. The use of this word, was, however, not common; for long after the Roman numerary system was broken down, *nummus* continued to be used as the generic term for the circulating medium.

The word "money" came into more general use during the Dark Ages, until with the scarcity, debasement and eventual almost entire disuse of coins, it was superseded by species; meaning, literally, payment in kind, but afterward in the form of specie, applied to coins and bullion. This word "species" was the lowest and grossest term employed to express the circulating medium of the times, the word *nummus* or "numbers," of the Roman Commonwealth, having been the highest and most refined. With the mediæval period, which fostered the Dark Ages and the reuse of coins, which the reopening of the Roman silver mines in Germany and elsewhere rendered possible, the word "money" again came into use, and being always associated with the precious metals, conveyed no meaning apart from them, and previous to the present century signified only so much gold and silver; this being the definition given to it by all of the earlier, and many of the later, economists.

With the general restoration of peace, the return of security, and the consequent use of corporative and governmental credits for the purposes of a circulating medium, the meaning of money has been amplified, and it is now generally understood to include any description of circulating media, whether coins, promissory bills, or irredeemable notes, otherwise nummaries or numeraries.

But perhaps the most extraordinary and interesting term in our vocabulary is "value." Everybody uses it, yet nobody appears to be certain of its meaning. For 100 years the ablest intellects in the world, Adam Smith, Chevalier Storch, Daniel Ricardo, Jean Baptiste Say, Frederic Bastiat, John Stuart Mill, and a host of lesser lights, have tried to agree upon a definition of value, but in vain. The entire science of political economy is built upon it; the practical affairs of government hinge upon it; an important agency of man's welfare (a good monetary system) waits upon it; and yet no man has satisfactorily analysed it. Although derived from the Latin word *valere*, the word "value" was not used by the Romans in its present sense. It came into use with the specie money of the Dark Ages, and previous to the time of Bastiat, scarcely 30 years ago, was generally construed to mean that attribute of a thing which was derived from its materiality and durability, or from the cost of its production (labor), or from its usefulness (utility), or from its desirability. These are the opinions, respectively, of Adam Smith, Ricardo, Jean Baptiste Say, and Chevalier Storch.*

But an application of these views to facts, showed all of them to be faulty. Light and air have, in the sense meant, neither materiality nor durability, nevertheless we concede the value of, and are ready to pay for, both illumination and ventilation. Neither buyer nor seller consults the cost of production; or else gold would never be bought, nor diamonds sold at their market prices, for one costs more than it will fetch and the other less. As for utility, it would be difficult to find more than the merest traces of it, in those works of art and luxury, which possess the highest value; and if we look for value in desirability, land, and water, and a myriad of other things, which necessarily form the first objects of man's desire, but which nature has supplied to him so liberally that they possess little or no value, arise to confute the definition.

Unable to digest the word as a whole, the economists attempted to manage it in parts. They split it into pieces, calling one *value in use*, another *value in exchange*, and so on, until each piece was small enough for their purpose; but, still in vain, there always remained a doubtful mass which they could not dispose of, and which constituted the enigma of the science they had attempted to construct.

Said Bastiat: "The primary element of exchange, is the notion of value; so that every truth, and every error which this word introduces into men's minds, is a social truth or error;" and "*value* is to political economy, what numeration is to arithemetic," and "economical science is condensed, and summed up in the word *value*, of which it is only a lengthened explanation."

In one masterly survey of the whole subject, this gifted philosopher swept away all the vague and many of the erroneous notions of value that had preceded him. He held that value was not an attribute, but a relation of things; that it implied "comparison, appreciation, estimation, *measure;*" or, as he otherwise explained it, "value is the relation of two services exchanged."

This view was a great step in the right direction. It was something to know that value was a relation, and not a thing, nor a mysterious issue of the attributes of things; it would have been more satisfactory had Bastiat informed us precisely what that relation was, but he died before his treatise on value was completed; and, judging from its appearance, probably, without revising the portion he had written. If an effort he now made to complete this work, it is hoped it will be viewed with the indulgence due to the earnest enquirer into any difficult subject.

In the first place it must be said that Bastiat's definition is hardly broad enough. Why should value be held to exist only between two services exchanged; why not between all services, and commodities exchangeable? The edifice which now shelters us, is not exchanged, nor being exchanged, yet it has a value; and that value is determined not by comparing it merely with the thing that may be offered in exchange for it, but, through the medium of money, by comparison with all other things which are exchangeable.

Value therefore exists not merely between two commodities, or services, but between all of such; and it exists not merely between things which are exchanged, but between all things which are exchangeable. The notion, common to other economists besides Bastiat, that money measures the value only of those things which are in market, up for sale, or being exchanged, is doubtless derived from the disparity between the magnitude of all commodities and available services, and the littleness of the measure—the mass of money—which forms their nominal equivalent. It would be equally absurd to hold, that gallons measure only wines which are being exchanged. The mass of money is of its present magnitude simply because it was so chosen to be, or so left to become; it can be made larger or smaller at man's pleasure, whenever he chooses to exercise the same dominion over it, that he has chosen to exercise over weights and measures; that is, whenever he chooses to define, and limit by law, the unit of measure, which, in the case of money, is the whole mass. Should this limitation increase or diminish the magnitude of the existing mass of money, this will not alter value, but only the expression of it in money, to wit, price. So, too, the gallon measure is of its present size, because it was so chosen to be; it would answer the same purpose, and prove equally efficient; no matter what its size was; only, in case of change, the expression of total gallons would be different. The quantitative and qualitative relations between all other things would remain precisely the same as before. But whatever the origin of the belief, it is evidently erroneous. The fact is, that nothing is being exchanged. It never can be said to be 12 o'clock, for time passes eternally; and, whilst we speak, nay, whilst we observe the clock, time has gone on, and escaped fixture. The act of exchange, indeed all actions, are equally unfixable, and if value pertained to objects only during the act of exchange, it would practically not pertain to them at all.

[But without attempting to follow the speaker through his argument, we give his conclusion. —Editors Press.]

Having thus determined what value is—namely, number, or the combined quantitative and qualitative relation between commodities and services—having at least attached to it a definite and precise meaning—it is now in order to turn to the evolution of the word. The course of this evolution has been already adverted to; but it has not been traced so fully as might be desired. What value represented to the archaic mind, we have no means of ascertaining. To the polished Greeks of Aristotle's time, we know, from his use of it, that it meant something akin to what we have defined; and so, also, it evidently meant to the Romans of the Commonwealth; for this is indicated by the root of the word *valeo*, or power, the power of numbers, for example. But from this time forward, it gradually came to have a more material meaning attached to it; until, in the obscurity of the Dark Ages, it came, at last, to mean a thing; and money, to represent it, was not money, unless it was also a thing; in other words composed of some commodity, as slaves, cattle, corn, gold or silver; and valuable only in proportion to the quantity of such commodity, as gold or siver, it contained. With the revival of learning, and the study of political economy, the grossness of this opinion rendered it no longer tenable; and yet, such was the difficulty of rising to the refined view of the ancients, that though it was evident that value was not a material thing, no one ventured to state just what it was. Its description was therefore attempted by circumlocution. It was shown that it originated in this or that way, or that it appeared or disappeared under this or that set of circumstances; but what it *was*, no one attempted to assert before Bastiat. With the correct assertion of its nature, namely, that of a relation between commodities and services, that philosopher stopped short. Precisely what that relation was, continued to remain the enigma of political economy; and it remains so to this day, unless the explanation herein attempted shall have the good fortune to gain general assent.

The evolution of this word has therefore kept pace with the evolution of European society. We—as Europeans—have but recently emerged from the Feudal Ages. The revolution in France, occurred less than a century ago; and feudal tenures and feudal survivals, together with feudal institutions and feudal forms of speech, are still closely interwoven in the texture of our practical life and vernacular tongues. Although some of us—we Americans, for example—have enjoyed the priceless boon of political liberty for several generations, we have scarcely yet had time to learn its deep significance—for what are a few generations of time in the life of a race?—and still less have we been able to throw off those invisible bonds, which shackle our social life, in the form of words that were cast or altered in the mold of mediæval ignorance and mediæval oppression.

*Bastiat, "Harmonies of Political Economy," p. 109.

Effect of the Imagination.—Sir Humphrey Davy, in his young days, assisted Dr. Beddoes, who at that time was bent on curing all diseases by the inhalation of gases. It so happened that Davy was accustomed, before applying the inhaler, to ascertain the temperature by placing a thermometer under the tongue. While thus employed on a countryman, who fancied this was the wonderful process he had heard of, the man exclaimed that he already felt better. Davy took the hint, left the thermometer in its place some time, and reapplied it every morning. His patient improved in health, and ultimately got quite well, without any other treatment.

Uniformity in Wire Gauge.—At a meeting of the Glasgow Chamber of Commerce, held recently, a report was submitted with reference to the desirability of establishing a uniform wire gauge. In the report it was suggested that the Chamber should concur with the Birmingham Chamber, in asking Parliament to supplement the Weights and Measure Act, 1878, by a clause instituting a legal standard to be recognized as a wire gauge.

The Cone-bearers, or Evergreen Trees of California.—No. 2.

[Written for the RURAL PRESS by J. G. LEMMON.]

Classification.

One of the earliest and most elaborate authors to treat of conifers was London, who (1st Edition in 1838) published his renowned "Arboretum." In it he describes all the genera and species known at the time, and distributes them as follows: North America, 40 species; Asia, 19; Europe, 14; Africa, 2; South America, 2; Australia, 2; Europe and Africa, 1; total, 80 species. It will be noticed that 40 species, one-half of the whole number, was ascribed to North America. Of these, 18 species were found in the United States.

Later, in 1853, Lindley's great work appeared, in which the number of species described was more than doubled, so actively had the work of exploration and scientific description been carried on during the preceding decade. These species were found to be distributed in about the same ratio—one-half of them being in North America.

One of the latest and most voluminous enumerations of the conifer family is by George Gordon, of England, in his splendid work, "The Pinetum." In it he describes 52 genera and 460 species.

But all these authors have followed precedent too much, and been limited in their researches by want of instruments and other helps, particularly good and abundant specimens, they being so difficult to prepare and so unwieldly to transport. Within a few years the discovery and application of the microscope has rendered necessary a thorough revisal and rearrangement of most of our sciences, especially those relating to natural history.

Scientists, aided by these helps, are arising here and there with special ability to grapple with most abstruse and formidable subjects. In the realm of botany alone, no one mind, either in Europe or America, is equally familiar with all its fields. The strongest minds are content with the mastery of a small class, a genus, or even a single species of plants. Compilers unite the work of these masters, and thus give to the world what would be a superhuman effort if contemplated by any one mind. And thus each of these specialists becomes an authority in the field of his exhaustive research, to whom all others must defer. To become such an authority it is only necessary to excel all precedent.

Authorities.

A few of these "authorities" may be mentioned: Sir Joseph D. Hooker, of England, forest trees; Dr. George Engelmann, of St. Louis, American forest trees; Prof. Asa Gray, of Cambridge, *gamopetalæ*, and especially of the immense order of *compositæ*; Prof. Daniel C. Eaton, of New Haven, lilies and ferns; Prof. W. G. Farlow, of New Haven, fungi and seaweeds *(algæ)*; Prof. George Vasey, of Washington, grasses; Prof. H. N. Bolander, of San Francisco, cryptogams and grasses of California; Mr. Anderssen, of Copenhagen, Eastern willows; Mr. M. S. Bebb, of Illinois, Western willows; Dr. H. W. Harkness, of Sacramento, fungi of California; Dr. C. L. Anderson, of Santa Cruz, sea-weeds of California; Leo Lesquereax, of Columbus, Ohio, mosses; Prof. Sereno Watson, of Cambridge, *apetalæ*; Prof. William H. Brewer, of New Haven, *polypetalæ*.

Orders of the Gymnospermæ

Authorities differ widely in the limits prescribed for the *coniferæ*, and as the rest of the *gymnosperms* are but few, it will be best to present the whole great class of *gymnospermæ*, or naked-seeded plants, comprising four orders:

1. *Pinaceæ*—Containing the three large tribes of *abietineæ*, *cupresseæ* and *junipereæ*.

2. *Taxaceæ*—The yew family, mostly found in the Eastern hemisphere; two species in California.

3. *Gnetaceæ*—The joint-stem family, mostly Asiatic; two species in California.

4. *Cycadaceæ*—Palm-pine; tropical; propagated in greenhouse; none indigenous.

Order 1. *Pinaceæ* (true conifers) *Tribe 1, Abietineæ*. Pine family. Fruit, a cone or strobile of numerous carpellary scales from the axil of a bract, arranged spirally around a more or less elongated axis. Contains four large genera.

1st genus—*Pinus* (from "pin," a point). Cone-scale on an elongated axis, leaves acerose, persistent, in fascicles, (single in one species), sheathed at base, each fascicle composed of 2, 3 or 5 leaves.

Species of Pine.

The entire number of species of pine throughout the globe is 92; in United States, 18; in California, 15; mostly discovered and named by the English explorer, David Douglas.

Species conveniently arranged by their leaves into three divisions. Species in each division distinguished by their cones, barks, etc.

Division A. Monæ—1-Leaved, Double.

1. *Pinus monophylla*, Torr. "Nut pine," of Nevada and eastern California foothills. Cone small, 2 to 3 inches thick, globular; esteemed for food by Indians. Timber very resinous. All parts of the tree strong-scented.

Division B. Binæ—2-Leaved, Short.

2. *Pinus contorta*, Doug. Improperly called "California tamarack;" high valleys; bark very thin; cone very small, 2 to 3 inches long.

2. (a) *Pinus contorta*, var. *Bolanderi*, "Bolander's pine; coast; cone smaller; thick, scaled, 2 inches long.

3. *Pinus muricata*, Don. "Bishop's pine;" coast; cone medium, very spiny, three inches long.

Division C. Ternatæ—3-Leaved Long.

4. *Pinus ponderosa*, Doug. "Yellow pine;" common; bark, yellowish; cone, medium; four to six inches long.

4 (a). *Pinus ponderosa*, var. *Jeffreyi*; "pitch pine;" high slopes; cones large, 6 to 8 inches long.

4 (b). *Pinus ponderosa*, var. *Benthamiana*. "Black pine;" near water; bark black; cone large, 6 to 8 inches long. These varieties run into each other imperceptibly, on the Sierra.

5. *Pinus insignis*, Doug. "Monterey pine;" coast and cultivated; cones medium, 3½ to 4 inches; close and hard; close-scaled, gibbous.

6. *Pinus tuberculata*, Don. "Knob-cone;" foothills; cones medium, 3 to 5 inches long; hard, close-scaled, gibbous, narrow.

7. *Pinus Sabiniana*, Doug. "Big cone" or "gray-leaf;" foothills; cones very large and heavy, 8 to 10 inches long; spines large and recurved.

8. *Pinus Coulteri*, Doug. "Spur cone"; southern coast; cones very large, 7 to 10 inches long; spines, curved upward.

9. *Pinus Torreyana*, Parry. "Torrey's pine" (rare). Southern coast; cones medium, close, spurless, 3 to 5 inches long.

Division D. Quinæ.—5-leaved, Short.

10. *Pinus Lambertiana*, Doug. "Sugar pine." Common; cones very large, 15 to 24 inches long, and soft-scaled.

11. *Pinus monticola*, Doug. "Mountain pine," or "white pine." High slopes; cones similar, but much smaller, 5 to 7 inches.

12. *Pinus albicaulis*, Engel. "White-stem" (rare). High peaks; cones small, 2 to 2½ inches long; globular, few seeded.

13. *Pinus flexilis*, James. "Bull pine" of Nevada. Cones medium, conical, 3 to 4 inches long.

14. *Pinus aristata*, Engel. "Bristle cone." Peaks; cones very small; spiny. Rare in California.

15. *Pinus Balfouriana*, Jef. "Balfour's pine" (rare). Shasta; cones medium; (little known).

[To be Continued.]

USEFUL INFORMATION.

Arsenic in Coal.

Dr. Stevenson Macadam read a very interesting paper before the Edinburg Pharmaceutical Society, "On the Presence of Arsenic in Soot," in the course of which the Doctor remarked that the coal consumed for household and general purposes invariably contained more or less sulphur in the form of iron pyrites, and that occasionally the quantity was so large as to be capable of detachment from the coal before the latter was sent into the market. The pyrites so obtained was commonly called "coal brasses." Dr. Macadam had recently had occasion to make some investigations as to the possible presence of arsenic in the atmosphere of towns, and it occurred to him that if the arsenic in the pyrites of the coal was volatilized with the sulphur, that probably evidence of such disengagement of arsenical vapor in coal smoke might be obtained by the analysis of soot. Accordingly, he procured a number of samples of soot, collected from different chimneys, and had no difficulty in determining the presence of arsenic in every sample. He mentioned that trials made on samples of soot taken at different hights in the same chimney proved that the arsenic was present in larger quantity in the soot collected near the fireplace than in those taken from the top of the chimney. From his results it was demonstrated that arsenic was evolved during the combustion of ordinary coal, and a part of it was condensed in the chimney along with the carbon and sulphur of the soot; but as a great part of ordinary coal smoke passes into the air there could be no doubt that a portion of the arsenic accompanied the smoke into the atmosphere. The more inferior a coal then, as a rule, the more pyrites it contained, and probably also the more arsenic. He must, therefore, reckon that every coal fire was a producer of arsenical vapor to a limited extent; but, notwithstanding the enormous quantity of coal consumed in towns, he was not prepared to say that the arsenical contamination of the atmosphere from that source was of any practical moment in a sanitary point of view.

INTENSE cold and pressure develops paraffine in crude petroleum, and thus we find that the pipe lines of the oil region have become so clogged with paraffine since the advent of the recent arctic wave, that they cannot transport oil in sufficient quantity to keep pace with the production. It is claimed that in the northern oil field alone from 5,000 to 8,000 barrels of oil are going to waste daily from this cause. In some cases the freezing is not so great as in others. This is owing to the oil being pumped through pipes sunk in the ground. The drilling and pumping wells have also, in many cases, been brought to a stand-still; partly because the streams which feed the boilers are frozen dry, and partly because the men cannot stand or work in the derricks with the temperature at or below zero.

CURIOUS FACTS ABOUT IRON.—Colonel Cazen, in a recent article on the subject, says: During his sojourn in the arm manufactories of St. Etienne and Tulle, at the central depot of artillery, and at the manufactory of Chatellerault, he was able to make important researches on iron. The fracture of iron may be nervous, in grains more or less fine, or in facets sometimes having a surface of several square millimeters; often it presents a mixture of these three features. Thus it is impossible to judge of the quality of an iron before breaking it; and it is on this account that in arm manufactories they break a certain number of bars with which they make a certain number of pieces for which they are intended, and which are afterwards broken to ascertain their resistance—that is, the goodness of the iron, which, moreover, is still rendered brittle in presence of phosphorus, arsenic, or sulphur. The best irons are the nervous, then those of fine grain and with facets. On railways it has been proved that rails placed in the direction of the magnetic meridian are affected quite differently from rails placed at right angles to this direction; the former oxidize and do not become brittle. In intermediate directions the rails participate more or less in the qualities of those which are placed in the two extreme directions. What becomes of the iron which is now so plentifully used in the construction of buildings—girders among others?

PIG-LEAD FROM SMOKE.—The following explanation is given as to how pig-lead may be produced from smoke: In the process of smelting the ore a great deal of it escapes in the form of lead fumes, and the White Lead Company was organized for the purpose of catching this smoke, and, by passing it through an almost endless line of pipes of sheet-iron and woolen bags, condense it. The result was that after an outlay of many thousand dollars and a year's experimenting, they have succeeded in condensing the smoke or lead fumes, into metallic lead, the same as steam is coverted into water. The product of the fumes is a bluish, impalpable powder, which makes a splendid blue paint, pronounced equal to the corroded article. For the purpose of making it white several furnaces were built, and the blue product, with the aid of an intense heat, is again changed into lead fumes, which are again condensed, and come out pure white lead. In the transforming of the blue lead into fumes, the object is to sublimize it all, but the heat is not powerful enough to do so.

HOW TO UTILIZE OLD FRUIT CANS.—Perhaps one of the most appropriate uses of an old fruit can that can be devised is to make it contribute to the growth of new fruit to fill new cans. This is done in the following manner: The can is pierced with one or more pin holes, and then sunk in the earth near the roots of the strawberry or tomato or other plants. The pin holes are to be of such size that when the can is filled with water the fluid can only escape into the ground very slowly. Thus a quart can, properly arranged, will extend its irrigation to the plant through a period of several days; the can is then refilled. Practical trials of this method of irrigation leave no doubt of its success. Plants thus watered flourish and yield the most bounteous returns throughout the longest droughts. In all warm localities, where water is scarce, the planting of old fruit cans, as here indicated, will be found profitable as a regular gardening operation.

DECORATION OF ZINC.—A chemical process for covering zinc with colored coatings has lately been described by Dr. L. Stille. The articles of zinc are first brightened by scouring with quartz sand, moistened with dilute muriatic acid, putting them quickly in water and then carefully wiping them dry with white blotting paper. To ensure success, however, it is necessary to employ zinc as free as possible from lead, and to have it as bright as a mirror. When these conditions are fulfilled the metal may be coated with a variety of beautiful colors by immersion in a solution of alkaline tartrate of copper for a shorter or longer interval of time, depending on the color that is desired.

GOOD HEALTH.

Snails for Medicine and as Food.

While snails are no longer an article of *materia medica*, says the *Phar. Jour.*, they are occasionally used in England, boiled in milk, as a popular remedy in diseases of the chest, simply, perhaps, for the reason that their mucilaginous properties are looked upon as likely to prove beneficial. But although snail soup is usually suggestive of the ludicrous to the English mind, M. Baron Barthelemy maintains that snails are capable of rendering valuable service in most chest complaints, bronchitis, asthma, etc., because, in his words, they contain "animalized sulphur, a little phosphate of lime, and especially carbonate, animalized, in solution, and in a nascent state in their mucilage."

M. Barthelemy made a specialty of snail preparations in his exhibit at the recent Paris exhibition. He displayed "snail syrup," "snail bonbons," and "helicine," as mucilage and powder. For these the edible snail *(Helix pomatia)* is used, and collected in the vineyards in the south of France (preferably in the months of August and September), and carefully preserved and fed during the winter.

He lays great stress on this feeding, and attributes the reason that these snails are not more generally used as an article of diet to the fact that their flavor is only properly developed where they obtain suitable food, as, for instance, in the vineyards of the south of France and Italy. However this may be, and whatever may be thought of the chemistry of this subject, it is certainly the fact that when this very mollusk was a titbit of the Roman epicure, it was, before being cooked, fattened in the *cochlearia* by means of a paste composed of meal and wine.

Action of Iron, Cod-Liver Oil, and Arsenic in the Blood.

Drs. E. S. Cutter and E. H. Bradford, of Boston, in an article in the *American Journal of Medical Sciences*, state that they have arrived at the following conclusions as to the effect upon the blood produced by administration of these drugs, both in health and disease:

1. In health, iron causes no increase in the number of the red corpuscles; but in the pathological state called anæmia there is an increase in the number of the red corpuscles under its use.

2. In the healthy subject, cod-liver oil causes an increase in the number of the red corpuscles, and a slight increase in the white. In certain pathological conditions this seems to be also the case if the medicine is well borne. If, however, the morbid process is active and the appetite is disturbed, the medicine does not appear to check the consequent anæmia.

3. Liquor potassæ arsenitis given in health caused a progressive decrease in the number of the red and the white corpuscles, that of the latter being most marked. In severe anæmia, on the contrary, there seems to be an increase at first of both red and white corpuscles. After a certain point there is a steady diminution of both, however. In the case of leucocythæmia there was a decrease in both red and white corpuscles, the decrease of the latter being very marked.

Edison's Cure for Neuralgia.

For the benefit of sufferers from neuralgia, we give Edison's recipe for his polyform, which is said to be remarkably successful in curing or deadening the pain of that terrible disease. It must be remembered that it is for outward application only: Chloroform, two ounces; chloral hydrate, two ounces; alcohol, one and a half ounces; camphor, one ounce; sulphuric ether, one ounce; sulphate morphine, six grains; oil peppermint, two drams. Shake thoroughly. It can be put up at any drug store.

The *Drug Reporter*, from which we clip the above, adds the following:

For Sciatic Rheumatism.—Iodido of potassium, two drams; cinnamou water, four ounces. Mix. Take one teaspoonful three times a day, before eating. It is also excellent for dyspepsia.

Cough Drops.—For an obstinate cough take syrup tolu, one ounce; paregoric, one ounce; mucilage gum arabic, one ounce; tincture tolu, two drams. Mix. For an adult, one teaspoonful two or three times a day. Half that quantity for a child.

These recipes are endorsed by the highest medical authority, and both are said, by the *Drug Reporter*, to have brought about some remarkable cures in a very brief space of time.

TIN-LINED STOMACHS.—"Yes," said a well-known chemist to a *World* reporter last evening, "people will have tin-lined stomachs before long." The chemist went to a closet and took therefrom several small bottles which he held up before a strong light. He exhibited several sheets of tin which had been extracted from sugar purchased from extensive dealers in sugar in this city. "This," said the chemist, "is what they use in the adulteration of sugar, and I am informed that some of the dealers buy it by the ton. This tin has been cut with muriatic acid, and was used in sugars and syrups. I have here (exhibiting some other small bottles) samples of glucose. From 25% to 30% is used in sugar and 65% in syrups. Poor starch and flour are also used by some of these wealthy sugar dealers, and I am informed that such adulterated sugars produce skin disease. Here is a bottle (exhibiting a reddish brown powder) that I cannot describe. I don't know what it is, but intend to find out. It was taken for sugar." The chemist is yet at work, and in a short time expects to make his report public.—*New York World.*

TOAD POISONING.—The following singular account of the action of toad poisoning on the human body, is reported in the last number of the London *Chemist:* A child of six years old followed a large toad on a hot summer's day, throwing stones at it. Suddenly he felt that the animal had spurted some moisture into his eye. There suddenly set in a slight pain and spasmodic twitching of the slightly injected eye, but two hours after coma, jumping sight, desire to bite, a dread of food and drink, constipation, abundant urine, great agitation manifested themselves, followed on the sixth day by sickness, apathy, and a kind of stupor, but with a regular pulse. Some days later, having become comparatively quiet, the boy left his bed; his eyes are injected, the skin dry, the pulse free from fever. He howls and behaves himself like a madman, sinks into imbecility and speechlessness, from which condition he never rallies.

MINING AND SCIENTIFIC PRESS.

The Week.

The rain, which commenced at this point about one week ago, has since continued, having come in such installments as have been calculated to effect the most good. We have had a number of smart showers and again some drizzle and mist, all of which has been absorbed by the thirsty earth, completely saturating the dry stratum on top and generally penetrating some distance below. This has made plowing possible everywhere, and so replenished the mountain streams that the hydraulic miners have now water enough for washing. As a consequence, great activity pervades this branch of mining, and the weather having been otherwise favorable for this class of operations, a good deal of gold dust is being taken out. Some of the quartz mills dependent upon water for their propulsive power, and which, through an insufficient supply bad, for some months before, been in a state of enforced idleness, have also started up since the advent of the rain, and are turning out bullion once more. Things along the California gold belt point now to an average good year. As a consequence, the miners are in much better spirits than they were but a week or two ago; something of this more cheerful condition of things in the interior having already been reflected upon the trade and general business interests of the city. Since our last issue the death of Dr. Linderman, Director of the United States Mints, is announced. This is an event that will generally be deplored and which will possibly cause the Government some inconvenience. Dr. Linderman, through his long connection with the mints, having been especially well qualified to fill the position he held.

The United States Geological and Geographical Surveys.

Bulletins 2, 3 and 4 of volume IV of "Hayden's Survey" have come to hand. The first of these contains a paper on the "Geographical Distribution of Mammalia, considered in relation to the principal ontological regions of the earth and the laws that govern animal life," by Joel A. Allen—which is of more than ordinary interest on the Pacific slope, in view of the facts that are being gathered here, touching the migrations and antecedents of our tertiary ancestors. It is only within quite recent years that the richness and value of our western and northwestern cordilleran lake and river deposits, of Cenozoic Age, have begun to be appreciated; and that the scattered knowledge that was extant in regard to the origin and relations of the Indian races, has at all been collated. So that there has never been at hand a convenient starting point for a study of the mammalian companionship on which we are obliged to rely for guidance in what may be fairly termed the geological history of our race. Mr. Allen's essay, though a critical study, merely of the realms of living mammalia, contains all the observations and deductions of the great naturalists, which are here harmonized, as far as possible.

We have had the local studies of Condon, Cope, Marsh, Hayden and Leidy, from fossil sources, along with Hector's, of the great dynamical changes whose marks are recorded in the flanks of the Rocky mountains; and as the world progresses, these, with other contributions yet to come, cannot fail to throw much light, in the near future, upon that important and central field—so far as the popular interest is concerned—of geological investigation.

The same number of Hayden's Bulletin contains an article by E. D. Cope, describing some of the "New Extinct Vertebrata from the Upper Tertiary and Dakota Formations." Many of them were collected by Charles H. Sternberg, Cope's assistant, recently in Oregon; others by Lucas and Condon, in Oregon; J. C. Isaac, in Montana; and John Collett, in Indiana. Zoological papers by Jordan, Cones, Thomas, Uhler, Edwards, Allen, Scudder and others, are plentifully represented in all of the Bulletins.

No. 3 contains an article on the "Mineralogy of Nevada," by Dr. W. J. Hoffman, based on collections made while he was connected with Wheeler's surveys in 1871. It is a valuable additions to our catalogues of determined minerals and available localities. Enough of this kind of work has been done—though it is all scattered and incomplete—to justify the hope that the Geological Section of the California Academy of Sciences will shortly collate a card catalogue of the obtainable minerals of the coast, with a view to facilitating private collection, by members, miners and mining students. Most of the minerals interesting to the coast in connection with ores or mining could be obtained and exchanged at a moderate cost, and with very little trouble.

Bulletin No. 4 contains paleontological papers by Scudder and White; and an article "On Some Striking Products of Erosion" in Colorado, by F. M. Endlich, the latter describing the chemical and mechanical methods in which nature is in the habit of producing some of her most remarkable scenic results.

These reports, along with those of the Wheeler and Powell Surveys, are distributed gratis by the Government, and are intended for the use not merely of observers and collecters, but of all those whose pursuits render it desirable or necessary for them to be familiar with the details of their fields of operation. While much of the matter in its original published form is necessarily technical and concise, popular forms and generalizations of a more universal interest, of this material in prolific crop, are sure to follow, and to reward and justify the wisdom of the Government in connection with these well conducted physiographical surveys.

Hayden has boldly invested the Rocky mountains, where he is unlocking their intricate mining and geological phenomena, from their most ancient and central core, through the various tilted mineral-bearing formations, to the flanking coal and placer concentrations of more recent times. King made a section of the plateau, including the essential features of all the cordilleran ranges. Wheeler, following the broader instincts of the old topographical corps of the army, takes in the geography and geology of the mining districts of the west, and appears to be concentrating his forces upon the western plateau and the country of the western range—the Sierra Nevada and Cascade mountains. Powell has an attachment for the brighter action of the great river valleys, with their human inhabitants. The United States Land Surveys—as yet unorganized physiographically—complete the list.

So far from these surveys interfering with each other, their fields are separate; and it is safe to say they are generally governed, in their scientific and engineering personnel, by motives of generous rivalry alone. Exceptional causes aside, it is undoubtedly necessary occasionally, in the public interest, to make common cause against mischief-makers, whose conceptions are narrow, or who are selfish enough to block the highways of progress; whose instincts are low enough to embroil their neighbors. While these surveys are receiving the consideration of Congress, however, the claims of the Pacific States and Territories to a general geographical and geological exploration, such as we have seen thus systematically begun, and auspiciously carried forward over a large portion of our new country, should never be lost sight of, nor allowed to be hindered in the least degree by any sinster causes. It is in this work—now leading and now following the busy industries and populations in whose interest it is carried forward—that the glory of the great conquest that is in progress, by our own generation of Argonauts, will culminate in one of the brightest pages of history.

Comstock Studies.

We noticed at some length the phenomena observed by Church in connection with the heat, as found in the depths of the Comstock lode. Equally interesting are his facts and deductions touching chemical action now in progress, giving rise to heat. In this connection he brings up an entirely new suggestion. Hitherto the only mode of producing heat that has been thought of, has been some process of oxidation, and about the only substances which are susceptible to this change are the metallic sulphides. Principal among these is pyrite, the sulphide of iron, one of the most common minerals of the world. Whenever a chemical source of heat has been sought this material has been vaguely referred to as the likely agent of its production. Prof. Church rejects this source of heat and on good grounds. He says:

"Wherever eruptive or plutonic rocks are found it is quite common to witness evidence, in the breaking out of hot springs, that heat agencies are still active within them, and this phenomenon is so frequently observed that hot springs are often referred to as the last phase of eruptive activity. The heat in the Comstock and other mines similarly situated is quite generally spoken of, for instance, as the feeble remnant of a temperature that once reached the point of rock fusion, but the facts encountered have compelled me to seek another explanation. It is impossible to assemble in an annual report all the data upon which this conclusion is based, but many of them will be given. They have led me to refer the high temperatures encountered in the mines not to the internal heat of the earth, nor to the residual heat of the rocks, which were once melted, but to chemical action now maintained in the erupted rocks.

"This action is not a combustion, for the oxidizable minerals in the lode and its accompanying rocks, the metallic sulphides, are little altered. In fact, the total quantity of pyrite and other sulphides is not large for the neighborhood of a mineral lode, but on the contrary, strikingly small, and not sufficient to maintain the heat of the rocks and water, except under circumstances of unusually rapid oxidation. That no metallic oxidation of any moment goes on in these rocks is susceptible of proof. The metallic sulphurets in the rock show little sign of decomposition, and this is true even in layers of the propylite, that are fissured and seamy and drenched with water, whether hot or cold. In fact, the preservation of the sulphur compounds, in presence of so much heat and moisture, is a noticeable fact, which I have frequently remarked in all the mines."

Several analyses of the mine waters are brought forward in proof of these assertions. The oxidation of pyrite produces the soluble sulphate of iron, and this would be precipitated by the lime of the rocks and form gypsum, which in its turn would be precipitated in cracks in the rock. Neither this nor the iron sulphate is found in any quantity, and Prof. Church concludes that the gypsum in the Savage water accounts for only two-thirds of 1% of the heat it contains.

The new explanation of the source from which heat in the earth's crust is derived carries important results with it. Whenever a liquid consolidates to a solid, heat is given out, and this fact plays an important part in the economy of the earth. Its most familiar illustration is the commonly observed fact that the appearance of snow often ends a severe spell of cold weather, the condensation of the moisture producing heat which warms the air. In precisely the same way the coolness which comes on at nightfall with the disappearance of the sun is modified by the condensation of the dew from the moisture which floated as vapor in the atmosphere.

The heat produced in the rocks is a consequence of the same law. The rainfall penetrates the rocks to a very great depth, good authorities not hesitating to acknowledge a percolation to the depth of 90,000 feet. It has also been proved by Dauhree that when silicate of alumina, which is the principal component of the Comstock rocks, is exposed to the action of water at great pressure, it takes up some of the water which combines with it chemically and produces clay, that being a hydrated silicate of alumina. In this process the fluid water becomes part of the solid clay, and gives out heat in its condensation.

Rain always dissolves the gases of the air in its descent. Carbonic acid, nitrogen and oxygen are all dissolved and carried with it into the crust of the earth, but when it solidifies these are liberated and take their way to the surface. Of course they are heated by the action that set them free, and we thus have streams of hot gas pouring through the rocks. It has been shown above that the transmitting power of the rocks is not sufficient to keep up the heat found in them, and Prof. Church's theory is that they are heated by these streams of hot gas. It is evident that close-grained rocks which give but little opportunity for the gases to pass, will not receive as much heat as those that are more open, and wherever broken rock is found that gives free passage to the gas through its crevices the heat will be highest. It is also a fact that has been observed, that wet rock does not pass gas at all. Rocks may be penetrated either by water or gas, but when the former has once entered, the latter is excluded unless the rock becomes dry again.

These facts are applied to explain some of the peculiarities of the Comstock. It is well known that some drifts are much hotter than others, and Prof. Church points out that whenever a drift lies in the shattered rock which often accompanies the black dyke, it is apt to be very hot. He also says that the hot spots of the lode lie in bands, and these bands he supposes to consist of shattered rock. He divides the country rock into two portions, the wet and the dry. The heat is generated in the wet rock by kaolinization, and the dry rock is heated by the passage of the resulting gases.

These facts are used to explain the puzzling differences which have hitherto vitiated the attempts to ascertain the rate of increase of temperature in the earth. It is often given at one degree for every 50, 60 or 70 feet of descent, but such statements lose sight of the figures which have been obtained. These run from 35 to 200 feet for one degree of increase, and no suggestion has ever been made before to account for the discrepancies. Even on the Comstock the rate varies according to the observations which are compared, and might be given at 25 feet or at 45½ feet to one degree. The latter rate seems to be the more correct, and this fact makes it quite improbable that we know anything trustworthy of the real rate of increase in the crust when the observations are in ground which is not liable to the peculiar conditions of the Comstock region, for there the rate is a maximum.

From this basis Prof. Church attempts to form an idea of the future fate of these mines. If the stories from the Comstock are to be believed, work in the mines will be almost impracticable if the heat increases to an important extent. Already we have reports of 140° and even 160° Fahr. in some drifts. But such accounts are probably inaccurate. No such temperatures are recorded in Prof. Church's work. He gives the temperature of most drifts at 108° to 116°, the latter for very long drifts. This of course is not the normal temperature, but that which obtains when a fair current of air is blown through them. Starting with the data given and allowing an increase of one degree for 45½ feet, the temperature of the rock at the 4000 level would be 174° Fahr. Inasmuch as the heat of the air is 108 to 116 degrees where the rock is 138 degrees, it is probable that the drifts on the 4000 level will not be above 130 to 140 degrees in temperature, and this may be modified to an important extent by altering and increasing the ventilation.

The great question is, will the heat increase below as fast as it has in the last 1,000 feet of depth, and will it rise to the boiling point of water? Our author says the data known is too vague to enable him to form an opinion on this important subject, but he has the impression that nothing in the known facts makes it certain that so high a heat will have to be met within the limits even of deep mining. The highest heat known in the mines is for air 154° in a closed drift, in the Crown Point 2000 level; and for water 154°, in the Savage and Hale & Norcross. While Prof. Church does not deny the possibility of finding still hotter water, he seems to have the impression that this may also be somewhere near the highest heating power of kaolinization at these depths. It is true that the water of Steamboat springs is boiling hot, but the sources of this may be near the surface where organic acids would play their part and increase the rapidity of the action. For these reasons he says that while the temperature of the rock and water may increase somewhat, it is not likely to rise to 212° Fahr.

As to the possibility of working in the increased heat of greater depths, the case of the Crown Point crosscut is an evidence that work can be done even at such excessive temperatures, and there is little doubt that means can be found to lessen the severity of the task.

These studies upon the cause of heat in the mines are only a subordinate part of Prof. Church's work. He has prepared a full account of the geology of the lode, in which the position of the bonanzas, the cause of ore as distinguished from barren quartz, the history of the lode's formation, and many other fundamental facts are discussed. This is accompanied with maps and sections of the great Gold Hill and Virginia bonanzas, showing clearly their true position in the lode. For the first time the position which the ore invariably occupies is made out, and the mode of searching for it is indicated. The true relation of the barren portions is shown, and the lode is proved to contain rich and barren zones placed in a certain order. This work is finished, and its publication may be looked for at an early day.

In 1878 there were 532 failures in California, of which 222 occured in this city, and 310 in other parts of the State. The liabilities were, in this city, $4,700,591; in other parts of the State, $6,899,539, making a total of $11,600,130. In 1877 the liabilities amounted in the aggregate to $11,736,276.

Well-Boring Machinery.

Our recent articles on artesian wells have interested many readers, if we can judge by the tenor of the comments upon them, which come in correspondents' letters. The obtaining of artesian water is of crowning importance in many localities, and this year there will be renewed interest in well-boring, because the season's rainfall promises to be rather scanty.

The engravings of well-boring appliances which we have given heretofore, and those which appear upon this page, will give readers a good idea of the manner in which the inventors have aided the well-borer in furnishing him effective apparatus. There is a point in favor of well-boring in this State, which is noted by an experienced Eastern well-borer. He writes us that after studying our descriptions of wells which have been sunk, he concludes that California well-borers have a marked advantage over their Eastern confreres, by reason of the different strata encountered here, as compared with those in the Eastern or Middle States. He refers to the bore at Fort Wayne, Indiana, which is over 3,000 feet deep, and fully two-thirds of that depth is solid rock. This proportion holds good throughout the entire oil-bearing region, and in fact, in all the older States where deep bores have been made. On the Pacific coast, the proportion of rock is very small, there being frequently but a few feet of hard rock, in a bore of several hundred feet. This difference in the formation necessitates the use of entirely different tools from those used in the Eastern States. The heavy rock-drilling outfits, costing hundreds of dollars, can be exchanged for a light attachment used on the derrick, and run by hand, or by spring pole or horse-power; the drills costing not over $50, and the attachment for man or horse, costing only from $10 to $60. These tools have been used to cut through hundreds of feet of rock, and they are said to work as fast as the more expensive ones.

It is a view of these cheaper devices for deep boring which we give on this page. They are the inventions of Oscar Rust, and are made and sold by the Rust Well Auger Company, of Macon, Missouri. They are said to have been fully tested and approved by the work which has been done with them at the East.

Fig. 1 represents auger worked by horse-power. When at work the upper end of shaft is always below the shreve, a pulley in the top of the derrick, and a swivel in the lower part of the rope near where it is attached to the auger preventing any twisting of rope, and gives the operator constant hold of the auger.

Figs. 2 and 3 show ordinary shallow well augers. They are made from 12 to 18 inches in diameter, and are calculated to work to the depth of 100 feet. Greater depths require smaller tools.

Fig. 4 shows wormer for loosening small boulders, cobble-stones and hard-packed gravel, and for working through hard-pan, slate, coal, soapstone, soft sandstone, or anything except solid hard rock. It is steel-pointed and warranted to do the work.

Fig. 5 shows the drill bit and reamer, in general use throughout the oil region in Ohio and Pennsylvania, and by artesian well borers throughout the Eastern States.

Fig. 6 shows an auger devised especially for artesian well boring. It is made of all steel, and is claimed to be the lightest running, fastest boring and most easily handled auger now in use. It is made from four to six feet long, and of any diameter from four to ten inches. By adding rubber belting valves at the bottom, and a small hook or hasp to hold the sides together in sand, a most effective sand auger is secured. The operator with this tool is enabled to penetrate clay, sand, gravel or any formation he may encounter except solid rock.

The augers here shown at Figs. 2, 3 and 6, each cut a hole from one-half inch to one inch larger than the body of the auger, thus giving free passage for air and water. These augers are especially calculated to work inside iron casing. The presence of the hard earth against the bits as the auger is being revolved, causes the bits or lower end of the sides to spring out a trifle, thereby cutting out under the casing, so the casing will easily settle. When the auger ceases to revolve and the hits no longer engage the earth, the sides spring back to their original position, and the auger comes up inside the casing. But if from any cause the sides do not spring in, a slight backward turn as the auger is being raised will press them in, and the loaded auger will come up perfectly free.

The sides of these augers hinge on a pivot-holt in the lower corners of the head, and are fastened by keys, as shown in the cut. To empty or discharge the load, the operator knocks out the keys, the auger swings open and the load drops in a cart or truck run under for that purpose.

A full set of horing tools, shown herewith, consisting of augers in Figs. 2 or 3 (any size), two turning levers, and the full derrick rig, consisting of two wheels, two axles, two cranks, four pair hoxes, one shreve or pulley and one swivel, costs $60. The auger shown at Fig. 6 is $10 extra. The shafting or rods used with these augers is two-inch gas pipe, with one length of solid squars iron above the ground for turning levers to attach to. These are furnished at 50 cents per foot when desired.

The couplings are all placed inside, and are simply a plug of two-iuch round iron, one end rivcted or welded in ous end of a gas-pipe, and the other end to be iuserted iu the end of the next length of gas-pipe, and fastened by two iron pins. The pipe is strengtheued at the piu holes by a baud of iron four iuches wide and one-quarter of an inch thick, shrunk over the end, ths pins passiog through tbe baud, pipe and coupling.

In lifting the auger from the bottom of the well, as each length of shafting comes above the ground, the coupling is loosened hy a blow of a hammer on each pin, and the length is lifted off and left standing in the derrick, without stopping ths aiger in its passage up, or 40 feet of shafting may be run out at the top of the derrick. These couplings are made at an expense of only about one dollar each; they are strong and durable, and aro said to be handled in one-fourth the time of any other.

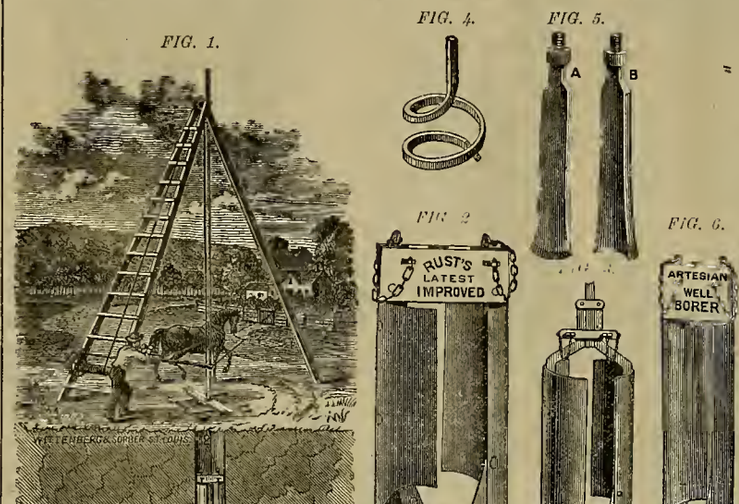
The Mechanics' Fair.

The Managers of the Mechanics' Institute decided, a short timo since, on holding another fair this year. As it has been customary every other year to offer premiums, and some were given last year, if the custom is followed, premiums will be given at the next coming exhibition.

If it is finally decided to do this, the premium list should be made out as soon as possible, in order that persons desirous of competing may have time for preparation. Cash premiums are, of course, the best and would, without doubt, tend greatly to increase the interest in the exhibition. There are a good many poor inventors who cannot afford to build machines and then attend to exhibiting them for five or six weeks for nothing. Many of this class would do so, however, if they saw any hopes of making a few hundred dollars. The Managers will probably take these facts into consideration and if possible offer a liberal premium list.

A quarterly meeting of the Institute will be held on February 6th, when it will be decided whether the annual election will take place March 1st or be deferred until June again. It is considered by some to be bad policy to change the Trustees just at the time preparations are being made for the fair. The intention is to change the time for annual elections so that the new board will either come in some time before or after the holding of the fair.

A Valuable Paper.—As usual, the San Francisco *Journal of Commerce* makes its appearance with the advent of the New Year, in the form of an enlarged edition, wherein the condition of our city trade, local industries, the general business of the country, and, in fact, nearly all of our material and commercial interests during the past year are reviewed and commented upon in an intelligent manner and in an exhaustive way. It is a paper that all interested in our physical well-being and progress should consult with care, and which should he extensively circulated abroad. Mr. Chas. G. Yale contributes to this annual an essay on the inlets, shoals, headlands, harbors, and other topographical and hydrograhic features of the Pacific coast. This article, which has been prepared with great care and with strict regard to well-established facts, should, because of its authoritative character and completeness, become exceedingly useful to government officials and our merchant marine. A large edition of this splendid paper has been issued and we believe mostly disposed of.



THE RUST ARTESIAN WELL BORING MACHINERY.

Smelting as a Business.

Editors Press:—I have had some experience in mining and assaying many kinds of ore, but have had no experience in base ores or smelting them. How long would it take me to learn as a basis for improvement, to assay smelting ores? I am thinking of going to Mexico or Arizona, and I wish to have some experience before starting. Will you state the shortest possible time for obtaining an insight, and also the cost.—M. H. S.

You knew, of course, that assaying and smelting are chemically the same process. It is the "art of separating" substances in the dry way—the reactions that the assayer and the smelter take advantage of being essentially similar to those employed in the wet way.

It is solution by means of fluxes and precipitation, after the reaction has taken place, by gravity. In smelting you have always to deal with silicates accompanying your ores or fluxes. Now to learn making assays by rote, for smelting any given kind or kinds of ore, could be shown you in a few hours; but that would not justify you in undertaking any new or unexpected ores, or products, that might come to your hand indiscriminately, or in setting up for an expert in this branch of practical chemistry.

While it is evident that you have before you the whole field of chemistry, which you must absolutely understand hy practical handling before you can properly understand the business of assaying and smelting—a study and a profession together that will take you many years to acquire—it is also true that you may be so fortunate as to find opportunities where some competent man of experience has worked out the details applicable to special cases, to a degree of simplicity that would enable a Chinaman speedily to acquire the process by rote.

By care and attention to the details of a particular class of ore to which he is accustomed, a laborer will learn to roast his material to an oxide, or to a sulphate, or a chloride to perfection.

You will have to find out first therefore what ores you intend to handle; and presuming it to be gold or silver that you wish to produce, what metallurgical process or processes will answer the best, under the circumstances existing in your mineral district; whether you will employ the cupola, or the reverberatory furnace for reduction; whether you will content yourself with smelting to matte; or whether you will also separate your lead, antimony and silver by other processes.

Not to lead you too far about the bush, you can find good teachers of assaying in this city who will show you the fluxes and how to use them, for from $10 to $100. You can go to the newly completed mining college of the University at Berkeley, for a term, and learn more about the whole matter, in the same space of time, and for the same money, than you can anywhere else.

If you wish to learn how to build a small Mexican mud cupola, and to run it; or how to build, charge, or run the kinds of furnaces employed in Inyo county, or at Eureka or Salt Lake, the most economical, and the surest way of gaining the best metallurgical practice, is to go to the University first, and then at once to the spot where some competent person has worked outthe details. They may apply to your case.

The shortest possible time necessary for "obtaining an insight" will be found to be where you invest your own money in operating smelting works, employing a practical Chinaman for head smelter.

Ducks and geese are very numerous in this section just now, says the Guadalupe *Telegraph*. Swans also abound, and are occasionally shot by our hunters. They are very fine eating.

The Geological Section.

The last meeting of this section was held January 11th, 1879, President Joseph Le Conte in the chair. The following members were present: Profs. Le Conte and Price, and Messrs. Bowman, Gibbes, Harding, Jackson, Keep and Christy. The following gentlemen were elected to membership in the section: Dr. G. F. Becker, Dr. Jas. Blake, Louis Falkman, Chas. G. Yale, R. H. Stretch, John T. Evans and F. Gutzkow.

A very interesting paper was read by Prof. Joseph Le Conte, entitled "The Mono Volcanoes and their Relation to the Glacial Drift." The paper is the result of several visits to this interesting region during the last few years, and as we intend shortly to publish it in full, we content ourselves with a brief extract for the present.

The paper began with a brief description of the Sierras in this region, of the gradually ascending slope of the range from the Sacramento basin, and the precipitous descent to the Mono plains on the east. The evidences of glacial action, the terminal moraines, etc., were mentioned. The waters of Mono lake were described as being strongly alkaline, containing a large excess of carbonate of soda with smaller quantities of chloride and borate of sodium, and carbonate of lime. The origin of these salts could be either the leaching of the basic volcanic rocks in the vicinity, or in the hot springs which still are active in the lake itself. It is certainly the concentrated residue of an immense inland lake which existed there during the glacial epoch. This is proved by the terraces which show the successive limits of the lake, and also by the immense clumps of a peculiar carbonate of lime, to which Clarence King has given the name of thinolite. Its crystalline form is the same as that of gay lussite, of which it is probably a pseudomorple. This supposition gives rise to some interesting speculation as to the changes which have taken place in the lake itself, in order to allow such a transformation.

The terraces, five or six in number, sometimes reaching in hight 600 feet, were spoken of. The bearing of this upon the size of the former lake was developed. The islands in the present lake were described; and the largest one was taken as in some degree typical. It was two and a half miles long hy one mile wide, and 300 feet high. It is composed of a finely stratified deposit of diatomaceous earth, overlying a basaltic rock, which is in some places exposed hy erosion.

The volcanoes, at present extinct, which exist upon the Mono plain, were next described. They are of a hight of from 200 to 2,700 feet. Some of them are as perfect as if just formed. The cone within a cone structure was described, and accounted for as being the result of eruptions taking place at different times.

The probable age of these extinct volcanoes was put as since the end of the glacial epoch, though their activity may have begun before this period.

In favor of this proposition, the following arguments were advanced:

1. The prodigious amount of glacial action which existed at this time would have otherwise croded them almost entirely, while they are on the contrary nearly perfectly preserved.

2. Sections of the plain made hy the creeks, such as that of Rush creek, which may be observed to the depth of 70 to 150 feet, show the evidences of glacial drift, while only upon the top is there any of the volcanic ash.

3. In the craters are found fragments of a rose-colored granite. These were probably ejected by the volcanic gases from the boulder drift which underlies the plains themselves and which was deposited during the glacial epoch.

4. Volcanic action in the region generally seems to have been most active during the tertiary.

The course of events which probably took place was then traced. The ancient lake extended over a vast area now laid bare. The glaciers when they touched the surface of the lake were broken off as icebergs, depositing their rocky debris upon the bottom of this vast lake. The gradual decrease of the body of the water as the glacial epoch came to a close, and the cycle of dryness ensued, was accompanied hy the advent of the volcanoes, and there was a continuation of the dry climate until the present condition of affairs came about. And finally, at the present time the curious fact was stated that there appears to he a gradual rise of the waters of this, as well as of other lakes in the neighborhood, as is shown by the gradual encroachment of the waters upon old trails, fences and other landmarks. This would seem to indicate that the cycle of dryness was coming to an end, and that a change of climate was imminent. Another evidence of increased precipitation was given in the condition of the terminal moraine of the glacier of Mt. Lyell. The front of the debris of the moraine is at its very limit of stability, which could not be unless the glacier had been advancing instead of retreating. The question arises, whether this is a sun-spot cycle or a geological one. Clarence King is of the opinion that it is a larger cycle than the former, as he finds that the snow avalanches of the high Sierras are invading the forests, in many cases tearing down trees that were 250 years old.

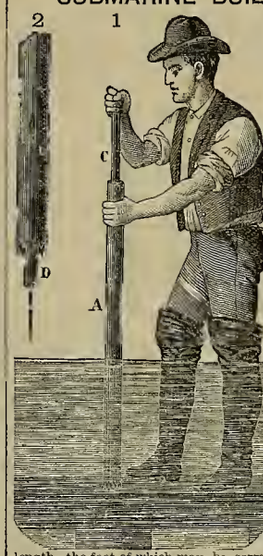
Important to Contractors
— AND —
SUBMARINE BUILDERS.



WILLIAM STACK, of Oakland, has recently patented through the MINING AND SCIENTIFIC PRESS Patent Agency, an apparatus for driving nails or spikes under water, an engraving of which is here shown. It is well-known that it is extremely difficult to drive nails or spikes under water, even if it is only submerged a few inches. These difficulties are completely obviated by Mr. Stack's device, which has been put in thorough practical operation in the construction of wharves and slips in the Oakland side of the bay.

Fig. 1 shows the application of the device, and Fig. 2 shows the construction. It is a metal tube of suitable length, the foot of which may be serrated as shown, so that the points will engage with the wood when the tube is pushed or driven against it. The rod or driver, *C*, has a recess or cavity, *D*, at the lower end so as to rest on top of the nail or spike shown in Fig. 2. Where the tube, *A*, is pushed against the timber in the desired position, the spike or nail is dropped in at the upper end and slides down against the timber. The rod, *C*, is then slid down on top of the nail, and by alternately drawing out and forcing the rod into the tube, the rod serves as a driver; or by hammering on the upper end of the rod the nail is driven into the wood. The tube answers both as a guide for the nail and driving rod. The tube can also answer as a guide for a screw-driving device on the end of the rod, by which lag screws may be put in place under water as well as nails. Of course the tube may be set in any position desired, so that nails may be driven at an angle if necessary. The appliance, as simple as it is, will be found very useful in many cases for bridge building or similar purposes. Address,

WM. STACK,
N. E Cor. Fifth and Harrison Sts., OAKLAND, Alameda County, California.

DEFLECTED HEAT!
Boswell's Combined Heater, Cooker, Baker, Clothes and Fruit Drier.

Combining the advantages of a Stove, Furnace, Oven, Dry House and Kitchen Range. An application of Scientific Principles to the economy of living, of labor, of health and of comfort. A handsome piece of Furniture adapted to the wants of every family. It equally economizes time, labor and fuel, and avoids exposure to heat in cooking as well as in baking. It bakes Bread, Cakes and Pies to any desired tint without turning or watching, or danger of burning. All odors produced in cooking are passed up the flue. Food cooked by deflected heat is improved in flavor, more easily digested, contains more nutriment, will keep fresh longer, and is also much improved in appearance. The stages of the cooking or baking can be seen without stooping or opening the doors of the oven. It will dry and bleach your clothes in from half an hour to one hour and a half, and heat your irons.
Fruit dried in the Boswell will gain from TWENTY to FORTY PER CENT. in WEIGHT, and THIRTY PER CENT. in QUALITY over that dried by any other process. It will successfully dry any kind of Fruit, Grapes, Berries, Meats, Fish, Vegetables, Coffee, Tobacco, Coru and Grain of all kinds.
— ALSO —
Boswell's Commercial Fruit Drier,
Used exclusively for drying and heating purposes ON A LARGE SCALE.
— ALSO —
BOSWELL'S CABINET HEATER,
Of all sizes and capacity for heating Private Residences, Hotels, Halls, School Houses, Churches, Offices, Stores, Railroad Cars, Hospitals, etc.
All of which can be operated successfully by a mere child, it is so simple in its construction, and with one-third the usual amount of fuel (coal or wood), used in any other heating, cooking or drying apparatus.
Every farmer and economical housekeeper should use it. It will pay for itself in the saving of fuel; it will pay in the superior character of its FRUIT DRYING, of its COOKING, ROASTING and BAKING; it will pay in its salubrious and healthful warm air; it will pay the rich and the poor alike.
Address, for Price List and descriptive illustrated circulars,
Boswell Pure Air Heater Co.,
No. 606 Montgomery Street, San Francisco, California.

EUGENE L. SULLIVAN, Pres't.

CAUTION
To Hydraulic Miners.
The public generally and Hydraulic Miners especially are hereby notified that any parties making or using the contrivance known as the HOSKIN DEFLECTOR will be prosecuted to the full extent of the law, said machine having been declared by the U. S. Circuit Court an infringement upon my patent, the
Bloomfield Deflecting Nozzle.
The public are also cautioned against using the Hoskin Deflector because of its danger to life and limb, this device having already occasioned several deaths and other serious accidents. The BLOOMFIELD DEFLECTOR is entirely safe, its two and a half years use without accident, as well as its construction, proves it to be a reliable contrivance.
Any parties wishing to purchase the right to use these Deflectors can do so by applying to the undersigned,
HENRY C. PERKINS,
North Bloomfield, Nevada Co., Cal., October 1st, 1878.

NATURE'S TRIUMPH!
CALIFORNIA
ROOT TEA
Is without a parallel in medicine. The most important discovery ever made in any age or country. It is the only perfect Liver and Blood Medicine ever known, has a powerful and heretofore unheard of influence on the circulation, and is extremely desirable in all forms of debility, local or general, and weakening and wasting diseases, effecting many astonishing cures when all else fails. It effects permanent cures of Blood Diseases which all the old Blood Medicines and the most powerful drugs fail to touch. A continuous influx of testimonials are daily pouring in from all sources.
Mrs. Lydia Read's Cure.
SAN FRANCISCO, January 13th, 1879.
DEAR SIR:—I feel it my duty to inform you what the California Root Tea has done for me, and think you ought to publish it for the benefit of others. I had been failing in health for years, and in spite of all the different treatment I underwent and medicines I swallowed had sunk so low that I could hardly walk across the floor, and felt that my time had come. When in this condition a few weeks ago the California Root Tea was recommended to me by a friend and I began its use. Its effect was most astonishing; it seemed *to actually build me up* from the start, and I am now as strong and hearty as ever. I am confident and so are my friends that had it not been for the California Root Tea I should now be in my grave. [Signed] MRS. LYDIA READ,
1843 Howard Street.
NOTE.—Mrs. Read's complaint was impoverishment of the blood, feeble circulation and a steady and persistent decline that defied the best physicians. For many such complaints there is no possibility of cure with anything heretofore known in medicine. Mrs. Read has resided at her present home for years, and is well known throughout the city as a lady of education and high standing.
The CALIFORNIA ROOT TEA is sold in packets, in its vegetable form. Each 50 cent packet makes a pint of balsam; dose, 2 spoonfuls 3 times daily. Any child prepares it in 10 minutes. Directions inside each packet.
All respectable Druggists and Grocers throughout the country sell it.

Barlow J. Smith, M. D.
Consulting Physician,
Professor of Phrenology and Mental Hygiene.
Proprietor of the Smithsonian Medical and Phrenological Institute, 635 California Street, above Kearny.
This Institute, by combining medical hygiene with the various Water Cure treatments and the most powerful Electrized Horseshoe Magnet in the world, claims to cure speedily and permanently all forms of acute or chronic nervo-vital derangements, Brain, Spinal and Heart diseases, St. Vitus Dance, Palsy, Epilepsy and all Rheumatic, Liver and Kidney troubles. The institution has for the past 20 years made a specialty of treating all forms of weaknesses and diseases peculiar to males and females. By the use of hygienic remedies and electro-motorpathy the worst forms of impotency and seminal weakness in males and sterility in females are speedily and permanently overcome. Hygienic board, with or without rooms. Terms moderate. Electro-thermal, Russe-Turkish and Medicated Baths given daily.
Mrs. Dr. Smith as Matron has charge of the female bathing department.
DR. SMITH has practiced Phrenology the past 30 years, and during the last 20 years has been constantly using the science connected with Physiognomy, in examining or diagnosing disease in this city, and claims to have made discoveries in the SCIENCE of Phrenology that enables him, by an examination of the head, even blindfolded, to determine the disease to which the person is constitutionally subject, or whether the disease at the time afflicting the person, is the result of accident or hereditary weakness; whether CONSUMPTIVE, DYSPEPTIC, RHEUMATIC, APOPLECTIC, NEURALGIC, LEUCORRHŒAL, or SEMINAL. Especially does the form of the head indicate the strength of the uterine, genital or reproductive system. The head is also an index of the natural strength of the lungs, heart, stomach, liver, kidneys, spleen, back or vertebra, and it determines the power of the system in warding off and overcoming disease of all kinds.
Ladies or gentlemen, desirous of obtaining a thorough and correct Phrenological examinations with Fowler and Wells' charts, will meet with a respectful reception at his consulting rooms. Parties can depend upon a reliable delineation of the character of their intimate mate or female friends, by presenting a clearly defined photograph.
Phrenological or Physiognomical examinations without charts, $1.50; with charts, from $2 to $3.
INVITATION TO INVALIDS
And all persons who are in any way out of health, who desire to know the nature and causes of their disease, may avail themselves of an examination through phrenology in regard to health free of charge, between the hours of 9 A. M. and 8 P. M. Sundays from 9 A. M. to 12 M.

Pocket Map of California and Nevada.
Compiled from the latest authentic sources, by Chas. Drayton Gibbs, C. E. This map comprises information obtained from the U. S. Coast and Land, Whitney's State Geological, and Railroad Surveys; and from the results of explorations made by R. S. Williamson, U. S. A., Henry Degroot, C. D. Cibbs and others. The scale is 18 miles to 1 inch. It gives the Judicial and U. S. Land Districts. It distinguishes the Townships and their subdivisions; the County Seats; The Military Posts; the Railroads built and proposed, and the limits of some of them; the occurrence of gold, silver, copper, quicksilver, tin, coal and oil. It has a section showing the hights of the principal mountains. The boundaries are clear and unmistakable, and the print good. 1878. Sold by DEWEY & CO. Price, postpaid, $2; to subscribers of this journal, until further notice, $1.

DIVIDEND NOTICE.
The German Savings and Loan Society.
For the half year ending this date, the Board of Directors of THE GERMAN SAVINGS AND LOAN SOCIETY has declared a Dividend on Term Deposits at the rate of seven and one-half (7½) per cent. per annum, and on Ordinary Deposits at the rate of six and one-fourth (6¼) per cent. per annum, free from Federal Taxes, and payable on and after the 15th day of January, 1879. By order.
GEORGE LETTE, Secretary.

507 Mechanical Movements.

Every mechanic Should have a copy of Brown's 507 Mechanical Movements, illustrated and described. Inventors, model makers and amateur mechanics and students, will find the work valuable far beyond its cost. Sold by DEWEY & Co., Patent Agents and publishers of MINING AND SCIENTIFIC PRESS, San Francisco. Price, $1, (post paid.

[Continued from Page 69.]

week more their new tramway will he completed and the ore will be conveyed from the mine to the mill in cars at a cost of about 30 cents per ton, and this will enable Mr. Crane to keep the mill running day and night, regardless of the weather. This company will soon have their smelting furnace ready for husiness, after which the stockholders may soon look for dividends, as this is sure to be one of the best mining properties on the coast, having more good ore now in sight than the company's mill can reduce in two years. At the Northern Light everything is moving along finely under Superintenñent Dunn, who is making the best of progress with his new tunnel, and everybody is waiting anxiously for this company to cut the ledge at this depth, which is sure to open up a wonderful body of ore. The tunnel in the Winthrop is being pushed forward, and when this company cuts their ledge, they will have mor. good ore above them than a 20-stamp mill can reduce in five years. There are many other valuable prospects that only require a few hundred dollars' worth of work done upon them to place them among the foremost mines of the district, as the surface outcrop and assays are extremely favorable.

SISKIYOU.

Cold Weather.—Yreka *Journal*, Jan. 20: The low temperature that has prevailed here, has for the time being put a pretty effectual check to mining operations of most kinds. For over a month past we have had colder weather than during any winter since 1856, the thermometer having heen below zero on two or three mornings, aud most of the time hut little ahove. In 1856, the thermometer ehowed 8° below zero on one morning at the old Yreka hotel, corner of Miner and Second streets, and there was good sleighing nearly all winter, a heavy snow storm having occurred on Christmas day, 1855. In 1852, there was even still colder weather aud more snow. We have had more snow during other winters since 1856 than the present, but the weather did not remain as cold for so long a period. For the past month, we have had a regular Eastern winter instead of a California winter, with its chapgeable weather and snow and rain together.

TUOLUMNE.

The Mines.—*Independent*, Jan. 25: Capt. Lombardo has struck "good rock" iu the Louisiana mine, a three-foot veiu, showing free gold iu several places along it. The "last shot" in the Spring Gulch mine hlew out rock that will go $20 to the pound. This is a good mine—the rock averaging, heretofore, $15 per ton. Should a strong company get hold of this mine, they would find it a paying iuvestment. It is rumored that D. T. Hughes is ahout to start up the Patterson mine again, at Tuttletown; and that arrangements to that effect are now beiug made. The vigorous working of this valuable mine would help brighten times at this end of the country. It is said that, last week, Tom White and Jim Gillis pounded some rich rock from their mine, at Tuttletown. The hand-mortar iu which the rock was "milled" yielded some $1,200.

TRINITY.

The Weather.—*Journal*, Jan. 25: The raiufall at Weaverville, to date, amounts to 10.40 inches. To this add 15¼ inches of snow, or about 1½ inches of water and we have the whole waterfall of the season, 11.64 inches. This will do for a starter, and with what may be expected hereafter, renders the mining prospect for the season pretty good.

NEVADA.

WASHOE DISTRICT.

Sierra Nevada.—Gold Hill *News*, Jan. 29: The south incline below the 2200 level is now down to the 2300, at which point a station will be opened and the main incliue will then be continued on down to the 2400 level. Just now the little donkey-engine at that winzo has all it can do to boist the rock while sinking the winze and running the north drift on the 2200 level. As sinking the winze to get down on the ore body is by far the most important portion of the work, it will be pressed ahead with all the vigor possible. During the first part of the week the incline passed out of the hard rock and cut into what appears to be another spur from the ore vein, showing good ore aloug with cap-rock, and other indications of the most favorable character. The north drift ou the 2200 level is advancing at tbe rate of three feet per day, the face in good running ground. There now appears to be but little danger of finding water on this level until the connection with tho north shaft shall have been completed.

Ophir.—The daily yield of ore from the 1600 and 2000 levels is being gradually incrcased to meet tbe increased crushiug facilities of the mills on the Carson river, which, owing to the late rain and snow storms, have beeu nearly doubled.

Consolidated Virginia.—The daily yield of ore is being gradually increased iu order to keep pace with tbe increased facilities for crushing, caused by the rise of water in the Carson river. The Trench mill at Silver City was added to the crushing force the first of the week and is now running steadily, crushing about 75 tons per day. The new pumps at the 2150 station of tho C. & C. shaft are in place, and will be ready to start up in a day or two more. An accident to one of the hoisting engines created a delay in the extraction of ore for a day or two during the first of the week.

California.—Daily yield, 280 tons of ore, which is being crushed at the mill as fast as it is extracted. The ore stopes on tbe 1700 and 1600 levels continue to show well and yield rich ore.

North Con. Virginia.—Car-load after car-load of the new hoisting aud pumping machinery is arriving almost daily on the ground and is heing placed in position ready for use as fast as the foundation pieces arrive. The entire machinery having heen set up at the manufactory in San Francisco, and tried before shipping, there is but little delay in putting it together. When the whole is in place ready to run it will cover a space 40x60 feet, resting on a solid bed of masonry 25 to 30 feet in depth. Sinking the main shaft is again makiug better speed. The tank station at the 1600 level is well under way and will soon be completed.

Julia Con.—The flow of water on the 2000 level continues unabated. Owing to necessary repairs to the guides in the main shaft but little hoisting of water could be accomplished during the week. At the same time a large 6-inch pipe to carry the compressed air from the 1200 down to the 1800 level has been put in. This will greatly increase the driving and ventilating power of both the 1800 and 2000 levels. The repairs to the main south drift on the 1800 level are completed, and a large chamber is being cut out for a winze, which is to be sunk in the ore vein down to the 2000 level. Portions of the water standing in the drifts on the 1800 level is disappearing down to the 2000 level.

Hale & Norcross.—The wiuze at the Combination shaft has connected with the top of the large water tank 30 feet helow the station, and the pipes in the lightning drift are heing jointed together ready to send the water from the Hale & Norcross through to the Combination shaft. Everything will be in complete order and pumping in good earnest will be commenced by to-morrow evening if nothing unusual happens to prevent.

Chollar-Combination Shaft.—The water has been drained from the bottom of the shaft and the sinking is making good progress. The flow of water is quite strong, hut ie easily handled by tho skeets, the pumps only taking the water down to the 2200 level. Everything is now in complete readiness, aud the pumps will without doubt begin takiug the water from the Hale & Norcross and Savage by to-morrow evening or the day after.

Sutro Tunnel.—The chances are in favor of hot water being sent through the tunnel, from the Hale & Norcross and Savage nines within the next day or two; also, of an injunctiou to stop it; also, that the pump columns of the Requa or Combination shaft may raise the water to the surface, ignoring the tunnel altogether. Meanwhile the south lateral branch of the tunnel is advaucing in good working ground, and will probably connect with the Julia shaft inside of the next two or three weeks. Total length of the branch to-day, 1,310 feet.

Belcher.—Excavation for the water tanks at the 2560 level nearly completed. Pump-bob at the 800 level is in place and works well.

Yellow Jacket.—New shaft has attained the depth of 2228 feet, aud has just 52 feet further to go to reach its connection with the drift cast on the 2200 level of the old mine.

Savage.—The water still stands in the main incline, 35 feet below the 2000 station. Everything is now iu complete readiness to commence pumping the water through to the Combiuation shaft. This will be probably done by to-morrow or next day at the farthest.

Utah.—The surface works are going steadily forward, the sole plates are ready for the reception of the engine beds, the huge spur wheel is being placed, and the pump-rod will he ready to lower into the incline in a very short time. Sinking the main incline below the 1350 level is making the usual fair rate of progress. It is now down 275 feet on the slope below the 1350 station.

Ward.—The new hoisting engines are all on the ground and are being placed in position ready for service as rapidly as the workmen can perform the job.

Gould & Curry.—Sinking the Osbiston shaft is making slow progress on account of the strong flow of water. It is now down 428 feet.

Bullion.—The face of tbe north drift on the 2400 level is in softer ground, but with no signs of water. Sinking main incline three feet per day.

Trojan.—Daily yield, 40 tons of ore, which is being shipped to the Vivian mill on tbe Carson river for reduction as fast as it ie taken out. The ehipment of bullion up to the 22d instant amounted to $6,880.30. The ore stopes on both the third and second station levels are looking well, and are yielding the usual quantity of good milling ore.

The following are a few of the more noticeable facts connected with the work of exploration in progress elsewhere along the Comstock lode during the past week. In the Morning Star, fiue quartz with some good ore. Water in Best & Belcher strong, and impedes sinking. In Mexican, Overman, Alta and Silver Hill work is going on as usual; machinery, etc., as a general thing, working smoothly and well.

ARIZONA.

Toombstone District.—*Citizen*, Jan 15: Therc is here no abatement of work, success and new arrivals. The saw-mill of the Toombstone G. & S. M. Co. bas been brought to perfect working, and on the 14th they commenced in earnest and are shipping lumber to the mill-site. The saw-mill is in the Huachuca mountains aud the mill is to be erected on the San Pedro about seven miles south of the junction of Babacomari creek. Distance of saw-mill to quartz-mill, 12 miles, down grade; will ship some 10,000 feet a day. The mill, which should soon reach Tuscon now, is to be 10-stamps. The company are at present doing most work on the Tough Nut, and have now exposed their fine ore body the entire length of the claim. On the Empire, Messrs Hooker and Stowe have sunk about 60 feet, defining a fine body of ore. These gentlemen have the claim bonded for $25,000, aud from the results of the work already done there is every prospect for completion of sale. Major Morgan's Merrimac is developing a fine ledge as work progresses. Mr. McCann is at work on the Head Center claim, owned by Messrs. Carpenter, Handy and others, with flattering prospects. This claim is just north of the Contention and adjoins it. Then, we believe, comes the Tranquility, then the Tough Nut; the fortunate owners of the Head Center have undoubtedly got a good property. The Brunswick mine is looking fine. It has been well prospected by two shafts and there are about a thousand tons of galena-silver ore on the dump. The superintendent, Mr. Ackerson, should be here this week, and upon his arrival some 10 to 20 tons of ore will be shipped to San Francisco per contract with Messrs. Edwards & Brown. The ore will be tested and will decide the character of the reduction works to be immediately thereupon erected at the mine. In the meantime work will be steadily prosecuted. The mine was purchased for the company last summer by Mr. R. H. Stretch.

The Juniper Range.—*Enterprise*, Jan. 18: Reports touching the new finds here are encouraging. The ledges are all large and well-defined, aud crop out strongly, some of them for miles. Shafts have been sunk on several of them to depths of 15 to 20 feet, and good assays obtained from the ore. Wood and water is pleutiful and the camp is easy of access. This section of our county has, up to the present time, been almost neglected by prospectors, but after these rich finds, we may expect a rush to the Juuiper range.

Tucson Mines.—*Star*, Jan. 9: The Bushell mine is showing some high grade ore. There are 8,000 to 10,000 tons of ore in sight in the mine, and the vein averages about three feet six inches all the way down. On the St. Louis they are runuing crosscuts each way at a depth of 50 feet. On tho south side have cut into the vein about four feet, showing a fine quality of ore. Ou north side will strike the vein at about 20 feet. Water is somewhat bothersome, hut they are pushing work. The Forsythe aud Rickard mines have just been incorporated and work commenced on them. They bave a pretty vein of 20 to 28 inches of good metal on the Forsythe and a four-foot vein on the Rickard.

Silver District.—*Expositor*, Jan. 18: Glowing accounts reacb us from this locality. The district is 60 miles from Yuma hy way of Castle Dome landing on the south side of the Colorado river; but by crossing the river at Yuma and going by way of the Picacho mill and again crossing the river, the distance is not more than 30 to 33 miles. The mines of this district aro situated from oue to seven miles from the Colorado river, and the ores are nearly all argentiferous galena. The country from the bank of the river affords every facility for good wagon roads, so that four men in from two to four days, can make a practicable wagon road to any of the mines yet discovered.

Outlook for the Year.

The days are filled with occasions for rejoicings. Since Wednesday evening a week ago the rains bave descended in copious measures upon parts of our State whicb have been lingering in tbe regions of droutb and despondency. The downfall has been most gentle and the thirsty earth has gained it all, until, in some parts, it is reported that the water from above has reacbed the moisture from below, and the circle of assured production ie complete. This is a theme for thanks beyond expression; for hoth in its immediate results and in indirect influences the surety of crops this year is of untold advantage to our State.

The indirect advantages to our State of a prosperous year, just at this time, are very marked. The tendency toward the reduction of tbe large holdings, by sales on easy terms to small purchasere will be wonderfully promoted. Half a dozen or more enterprises, which look directly toward increasing the number of our proprietary producers, will be pushed forward with vigor, and those who have already newly embarked upon the work of making new bomes, will find the skies brightened over them and labor lightened by its rewards. It is reported from the East that the clonds of protracted depression and "hard times" are surely lifting. California has never entered the dark valley as deeply as her Atlantic sisters, and she will be the quickest to answer the call to retreat toward the light, if local conditions are but favorable. Again, the industrial depression in Europe is said to be giving many men there the resolution to cast their lot with the nation which is now the world's favorite, tbe United States of America. The statistics of immigration at Castle Garden, New York, for the last few months, show that a tide which has long been unusual there, is rising. The claims of the States will be carefully scrutinized by the more intelligent of this throng of incomers, and California would cut but a sorry figure in their view with the load of a drouth upon her back. Happily this is not to be; and the widely-distributed rainfall will enable all parts of our State to vie with each other to secure their quotas of desirable citizens. California will greet her guests with a broadside of prosperity.

To all the diverse interests of our State, as well as to the tillers of the soil, the word will be: "Go forward." To legitimate mining enterprises, valuable as they are to the agriculturist in building up new local avenues of consumption, there will come increased confidence and capital. One would think that the experience of the last few months, if not former disasters, would lead the people toward the true and real instead of trusting to the sure destruction of street-mining in San Francisco. It cannot but be, that the influence of a good year in our producing interest, will be to attract toward the rewards of legitimate industry, which will be seen on every hand; for all kinds of legitimate business will be stimulated and pusbed forward. Manufactures will assume new life and new onee will be founded. Commerce will plume its wings for new flights, and all the satisfaction of work well done will come to the lot of our wide-awake and progressive people.

News in Brief.

Salmon are very abundant in tbe Russian river.

Colonel Ingersoll made $26,000 by lecturing last year.

Prospecting for gold and silver ie going on within two and a half miles of Calistoga.

Twelve tramps, ranging from 12 to 40 years of age, were taken in at Maryeville hy policemen lately.

About 600,000 tons of coal have been shipped from Astoria to San Francisco during the last year.

Subscriptions to the new four per cent. loan are being made at the rate of about $12,000,000 per day.

The water in the Straits of Gibraltar, at the depth of 670 fathoms, is four times as salt as at the surface.

The Coquille river wae frozen over at a point near its mouth during the late frost, the firet time for many years.

A Prague chemist has invented a mirror which reveals the conteuts of wine casks without removing the heads.

An English paper says that American-made lamps are more elegantly designed, and better finished, than their own.

Dye and Anderson, the murderers of Tullis, have been sentenced to be hanged at Sacramento on the 13th day of March next.

W. T. Tevis, a hunter of Petaluma, is said to have earned $350 in one month this season shooting quail for this market.

Portions of the interior prese earnestly admonish the farmers to avoid, as far as possible, running into debt at the country stores.

M. De. Lesseps has declared the flooding of the desert of Sahara practicable. Important Roman remains have just been discovered there.

The Santa Barbara *Press* thinks that the question of "pipe lines" will soon become an important one in the oil belt of southern California.

Gen. Bidwell is having arranged, under his own supervision, an immense poultry-yard, which is to cover over 100 acres of land, near Chico.

The honey crop of San Diego county in 1878 was more than 787 tons. San Diego county produces more honey than all the rest of the State taken together.

Every tenth person in a Hungarian town of 20,000 inhabitante has recently been attacked with diphtheria, and 927 bave died. The malady also prevails in Vienna.

The weather in Great Britain continuee severe, and the number of distressed poor ie greatly increased. In Paris traffic is almost suspended on account of the snow.

There are 272 telepbone statione under the direction of tbe German post-office authorities. The instruments work perfectly over lines 50 kilometers long—say 32 miles.

Great alarm prevails in Europe concerning the rapid spread of the black plague, and the most energetic measures are being taken to confine it to the regions already infected.

The banks of Montana paid $63,000 in express charges on gold and silver bullion shipped out in 1878, and the weight of the express matter brought into the Territory was 500,000 pounds.

The Oakland *Times* believes that the policy which has been followed by the Regents of the State University since the day of their organization has been far-seeing and wise.

Thirty years ago the profession of mining engineer was almost unknown in the United States; to day the American Institute of Mining Engineers numbers over 700 members.

France forbids the manufacture or sale of earthenware, whether French or foreign-glazed, with a layer of lead oxide melted or imperfectly vitrified, and so liable to yield lead to weak acids.

Engineers of steamships have found that the best lubricants are glycerine for the cylinders and castor-oil for the bearings. When castor-oil is used the main hearings seldom become heated.

Thus far the borings on tbe French coast in connection with tho proposed English Channel tunnel confirm the possibility of the execution of the scheme. The geological cousiderations are all favorable.

PATENTS AND INVENTIONS.

List of U. S. Patents Issued to Pacific Coast Inventors.

[From Official Reports for the Mining and Scientific Press, DEWEY & CO., Publishers and U. S. and Foreign Patent Agents.]

By Special Dispatch from Washington, D. C.

211,737.—Machine for Cleaning Fiber—T. McAuley, S. F., Jan. 28, 1879.

211,774.—Compressed Air Water Elevator—John Patten, Spruce Mountain, Nev., Jan. 28, 1879.

211,772.—Apparatus for Washing Chloridized Ores—D. J. O'Harra, Reno, Nev., Jan. 28, 1879.

211,702.—Cultivators—P. S. Russell, Riverside, Cal., Jan. 28, 1879.

211,750.—Rotary Vacuum Engines—L. B. Laurence, Monticello Cal., Jan. 28, 1879.

211,731.—Diaphragms for Ore Furnaces, M. D. Haskins, Guerneville, Cal., Jan. 28, 1879.

211,721.—Non-corrodible Composition for Quicksilver Condensers—H. B. Eames, S. F., Jan. 28, 1879.

211,030.—Horse Rake—Abby & Brammer, Livermore, Cal., Jan 28, 1879.

211,893.—Apparatus for Washing and Amalgamating Ores—C. Duhem, S. F., Feb. 4, 1879.

211,017.—Waste Pipe, Cut-off and Valve—Levake & Grubb, S. F., Feb. 4, 1879.

211,883.—Hoisting Register—H. C. Behr, Virginia City, Nev., Feb. 4, 1879.

211,885.—Railway Track—A. Bowman, Seattle, W. T., Feb. 4, 1879.

The "Great Basin."

John Muir, lectured on "The Great Basin," at Sacramento, January 14th. He was along with the Coast Survey triangulation party, which worked last summer between the Sierra Nevada and the Rocky mountains. Whether he has a large audience or a small one, Muir is equally certain to entertain it. In this instance it was quite a large one, including the Literary Instituto of Sacramento; and he kept it in close attention for two hours. "Mr. Muir," says the *Record-Union*, "is a simple, unskilled talker, a man who lives in the free air of the mountains, and whose highest ambition is to delve into the wondrous mysteries of nature. He talks to his audience simply, as if speaking to a small circle of friends."

This falls as far short of doing him justice in one way, as the oft repeated allusion to him as a "distinguished geologist," overrates him in another. He lays claim to nothing of the sort. Muir, is a poet and a philosopher, a rare conversationalist, and a skillful writer; withal a naturalist, and a geologist of modest pretensions with a good deal of merit, but, eapecially, entitled to the great credit of interesting everyone in his subject. He is truly, as has been said, the "Thoreau of the Sierra," and like Lassen, the Pioneer; Marshal, the Gold Finder; Adams, the Grizzly Bear; Fremont, the Hero; John Oakhurst, the Gambler; King, the "Mountaineer;" Hutchings, the "Yosemite Man;" Whitney, the great "Fisherman;" Avery, the gentle Word-Paiuter, and Seabough, of the San Andreas *Independent*, he has written his mark upon the olive hlue and snowy mountain side of the Californians.

Mrs. Derby, the widow of that genial humorist, Lieutenant "John Phœnix" Derby, went to Washington five years ago with $60,000, was persuaded to invest it in real estate, and has lost it all, and is said to be on the verge of insanity in consequence.

The Duty of the Hour.—Lest any reader should forget it, we mention the peculiar fitness of the season for renewing old subscriptions and making new ones to the Press. In going forward with our journal, we need the help of our patrons both with mind and money. Do not forget to send the printer his due, as the aggregate of small individual amounts will give him a force that wil make the types fairly dance into the lines. We trust that only a hint will be needed to rally the dollars, for with them assured we have a thousand themes to occupy our columns. Let all step up promptly to the Captain's office and then we will go out on deck for another year's voyage —*January 1st, 1879.*

Fresh attractions are constantly added to Woodward's Gardens, among which is Prof. Gruber's great educator, the Zoographicon. Each department increases daily, and the Pavilion performances are more popular than ever. All new novelties find a place at this wonderful resort. Prices remain as usual.

Artesian Wells Wanted.—Parties who are prepared to contract for boring artesian wells are invited to send terms to Edward Frisbie, proprietor of the Reading Ranch, Anderson, Shasta County, Cal.

Settlers and others wishing good farming lands for sure crops, are referred to Mr. Edward Frisbie, of Anderson, Shasta County, Cal., who has some 15,000 acres for sale in the Upper Sacramento valley. His advertisement appears from time to time in this paper.

Examine the accelerative endowment plan, as originated by the Mutual Benefit Life Insurance Co., of Newark, New Jersey. Assets, $30,533,429.04. Lewis C. Grover, President; L. Spencer Coble, Vice-President; Benjamin C. Miller, Treasurer; Edward A. Strong, Secretary; Bloomfield J. Miller, Actuary. Send for circulars to James Munsell, Jr., agent of insured, 224 Sansome St., San Francisco.

Experimental Machinery, drawings, patterns, models, all kinds of electrical and telegraphic apparatus to order. See ad. F. W. Fuller, 415 Market St., second floor, S. F.

Henry R. Ewald is our general correspondent and agent for Arizona.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

Cherokee Flat Blue Gravel Company.—

Location of principal place of business, San Francisco. Location of works, Cherokee Flat, Butte County, California.

Notice.—There is delinquent upon the following described stock, on account of assessment (No. 10), levied on the 20th day of December, 1878, the several amounts set opposite the names of the respective shareholders, as follows:

	No. Certificate.	No. Shares.	Amt.
A. Casselli	17	4608	$230 40
L. Nussbaum	105	50	2 50
E. I. Pfeiffer	106	430	21 50

And in accordance with law, and an order of the Board of Directors, made on the 20th day of December, 1878, so many shares of each parcel of such stock as may be necessary, will be sold at public auction, at the office of the company, on Tuesday, the 18th day of February, 1879, at the hour of two o'clock, P. M., of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of the sale.

R. N. VAN BRUNT, Secretary.

Office, No. 318 Pine Street, Room 6.

Griffith Consolidated Mill and Mining Com-

pany.—Location of principal place of business, San Francisco, California. Location of works, Diamond Springs Mining District, El Dorado County, California.

Notice is hereby given, that at a meeting of the Board of Trustees, held on the 2nd day of January, 1879, an assessment (No. 1) of twenty cents (20c) per share was levied upon the Capital stock of the Corporation, payable immediately to the Secretary, at the Office of the Company, Room 48, 330 Pine Street, San Francisco, California.

Any Stock upon which this Assessment shall remain unpaid on the 26th day of February, 1879, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on Wednesday, March 26th, 1879, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Trustees.

GEO. M. CONDEE, Sec'y.

Office, Room 48, 330 Pine Street, San Francisco, California.

Mariposa Land and Mining Company of

California.—Location of principal place of business, San Francisco, California. Location of works, Mariposa County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the tenth day of January, 1879, an assessment (No. 15) of One Dollar per share was levied upon the capital stock of the corporation, payable immediately in U. S. currency to the Secretary, at the office of the Company, Room 33, Nevada Block, No. 309 Montgomery St., San Francisco, Cal., or the Assistant Secretary at the office No. 9 Nassau St., New York, N. Y.

Any stock upon which this assessment shall remain unpaid the twelfth day of February, 1879, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on Wednesday, the twelfth day of March, 1879, to pay the delinquent assessment, together with cost of advertising and expenses of sale. By order of the Board of Directors. LEANDER LEAVITT, Sec'y.

Office, Room 33, Nevada Block, No. 309 Montgomery St., San Francisco, Cal.

Summit Mining Company.—Location of

Principal place of business, San Francisco, California. Location of works, Mineral Point Mining District, Plumas County, Cal.

Notice.—There are delinquent upon the following described stock, on account of assessment (No. 6,) levied on the 19th day of November, A. D., 1878, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Certificate.	No. Shares.	Amt.
Boring, I C	32	1200	$60 00
Bohn, John	150	200	10 00

Best Refined Cast-Steel.

Warranted Most Superior for Drills, Hammers, Etc.

A full and complete stock of this reliable and well-known brand of Steel, for mining and other uses, now in stock and for sale

At No. 417 Market St., S. F., - H. D. Morris, Agent.

Ingersoll Rock Drills.

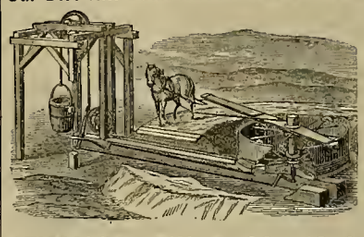
In use in the largest and best Mines of the Coast.

HAS AUTOMATIC FEED.

Has less Repairs.

Is Lighter and more Easily Adjusted than any other Drill.

Our DRY AIR COMPRESSORS are the most Economical Compressors in the Market.



MINERS' HORSE-POWER.

This Power is especially adapted to working mines, hoisting coal or building material, etc. It will do the work of a Steam Engine with one-tenth the expense. One Horse can easily hoist over 1,000 pounds at a depth of 500 feet.

The Power is mainly built of wrought iron, and cannot be affected by exposure. The hoisting drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

SAN FRANCISCO, SATURDAY, FEBRUARY 8, 1879.

VOLUME XXXVIII Number 6.

Oil Wells of Ventura County.

The searchers after petroleum in our central southerly coast counties are deserving of success, and according to recent reports from that quarter some of them are beginning to realize a pretty good share of it. According to the Ventura *Signal* they have struck a body of oil in the Los Angeles well on the Little Sespe, which, at a depth of 1,514 feet, flows 110 barrels per day. This oil is represented to be perfectly clear and of the best quality, with a specific gravity varying from 39 to 41 degrees. After filling all their tanks, having a holding capacity of 300 barrels, the flow has been stopped till additional tankage can be obtained. Six months have been spent in boring this well. At 1,387 feet 10 barrels per day was got, and a good show thence to the present depth. About 85% of the product here is used for burning, lubricating, etc., and the balance for fuel; being also thought to contain much paraffine. The oil belt here occupies a sort of basin, of which the Los Angeles company own 820 acres, besides the Tar creek tract, considered still more valuable. In this basin, where it is believed 300 wells might be sunk without crowding, is situated the "Petroleum Park" claim of 16 acres, also very promising land which is owned by San Francisco and Los Angeles parties. Machinery is about to be placed on this property for well boring, a somewhat costly road having been built for the purpose of getting it in, also shops, suitable buildings for the accommodation of workmen, etc. This locality is distant from Ventura 25 miles, and is elevated above sea level 1,525 feet. It is, however, but 225 feet above the mouth of the canyon, from which it is distant 7,000 feet. The Sespe, a branch of the Santa Clara river, carries a considerable quantity of water and runs close by the well. The company will pipe their oil to the mouth of the canyon, where their receiving tanks will be erected. Ultimately it is expected that the oil will be piped all the way to Ventura, the country being favorable for the purpose. As other wells will be opened here, the product of this locality will amply justify the expense of laying down a main pipe to the above point. To this pipe "Petroleum Park," and various other fertile districts in the vicinity, would become tributary. In this mild climate such pipes would never freeze nor would the oil clog. At Ventura, it is presumed that extensive oil refineries would be built, greatly benefiting that place and the surrounding country. With this mineral oil in such abundance, it would probably soon supersede coal and wood as a steam generating fuel. Capt. Roberts, Superintendent of the Los Angeles company, using it successfully in the furnaces at the well. Four barrels of crude oil go as far as two and a half cords of good live oak wood. This oil the company can, and, in fact, proposes to furnish in any quantity at one dollar per barrel. The gas companies of the larger cities will also, it is thought, substitute petroleum for coal, as there is more gas in a barrel of this substance than in a ton of coal. Schooners can be so constructed as to carry oil in tanks, which may be filled from pipes on the wharf, or it can be carried cheaply as ballast. After the burning fluid comes the lubricating oil, which is graded from the finest used on sewing machines, etc., down to car axles and wagons. It is in use on the Central Pacific road, and the "Star Oil Company" is supplying some large establishments in San Francisco. The refuse is used for fuel.

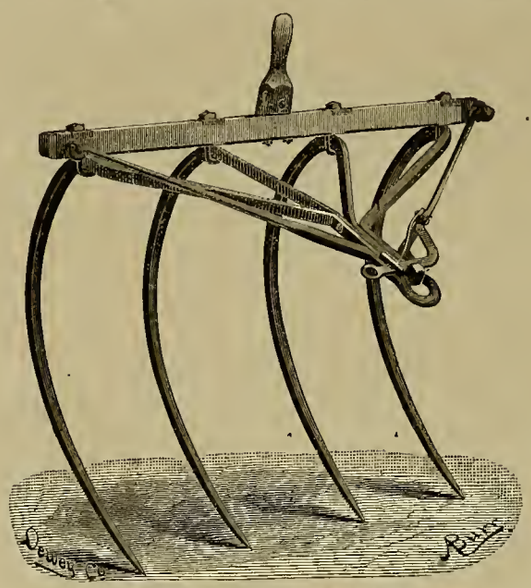
CAVES IN AMADOR.—A remarkable cave was discovered not long since at the mouth of a marble quarry near Jackson, Amador county. It appears now from a notice in the *Ledger* that another cave has been found in that vicinity, being on the Consumnes, opposite Slug gulch. It has been explored for a distance of 3,000 feet, and no end found. The passage is small, as are also the chambers which have been explored. But the mystery of the cave is that a strong current of air sweeps through the main passage, making it very difficult to carry a torch. Another inexplicable circumstance is that far below can be heard the noise of falling water, as if rushing through the rocks to some outlet which has not yet been found.

The Allen Governor.

This governor has won several prize medals, on different exhibitions, and is especially useful in controlling and regulating all kinds of link motions and variable cut-off engines—including the Corliss (to which it is particularly adapted), and all the engines subject to great variations. Engines to which it is attached run with the throttle wide open. And to whatever changes or steam pressure, or changes, however sudden, in power used, the engine may be subjected, it should not vary more than one revolution as long as there is sufficient steam to do the work. These governors may be seen at the Pacific Iron Works, and their operation is as follows:

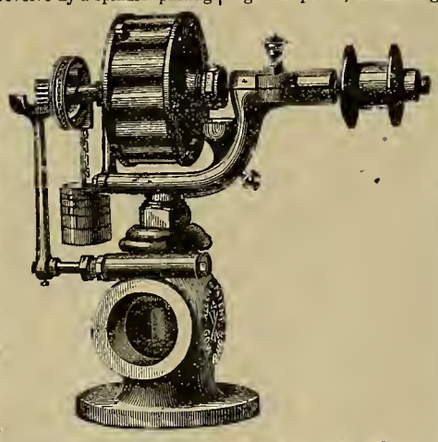
Within a corrugated cylinder, which has small projecting ribs on its interior periphery, and which is partially filled with oil, a paddle-wheel is caused to revolve by a spindle passing through one end of the cylinder, driven by a belt communicating with the fly-wheel shaft. The tendency of the revolving paddle-wheel is to cause the cylinder to move in the same direction. On the opposite side to the revolving spindle is a trunnion or short spindle fixed to the cylinder, attached to which is a wheel carrying a set of movable weights suspended by a chain, the speed of the engine being regulated by the number of weights. Attached to the wheel and keyed on the end of the short spindle is a pinion revolving with the cylinder, and working in a toothed sector, the arm of which, being fixed on the spindle of the throttle-valve, opens or closes it as the oil cylinder moves with the paddle, according to the variation of load thrown on the engine. When used with variable cut-off engine, the arm is attached direct to the cut-off.

From the above brief description of the Allen governor, it will be readily understood that its principles are in accordance with natural laws. It will be seen that the weights are raised and lowered in a nearly vertical line, and unlike those of other governors, remain the same at every point of their suspension. The high rate of speed used acts advantageously in making the governor very sensitive; and, all parts being lubricated, it works with the smallest amount of friction. The centrifugal or ball principle being entirely abandoned, the movable weights are suspended as easily at one point as another, by the action of the paddle-wheel in the oil cylinder; and from this fact, together with others peculiar to its construction, it offers a direct saving of fuel, and a considerable increase in the power of the engine.



HARRISON'S IMPROVED HAY FORK.

The peculiar action of this governor, which admits of the use of a valve of large area, thereby admitting to the engine cylinder the greatest possible boiler pressure at each stroke of the piston, has produced great results by being attached to old engines, greatly increasing their power, or effecting a direct saving in fuel, and in hundreds of instances doing both. In running an engine with this governor, with high or low pressure of steam and with all variations of power, the throttle is opened wide in the morning and remains so until closed at night, thus relieving the engineer from all labor and care, except keeping the engine oiled, and giving him a great deal of time for other duties.



THE ALLEN GOVERNOR AND VALVE.

Allen's patent governor valve is constructed with a double disc in a tubular form, and is perfectly balanced, there being no spindle, as in the ordinary throttle-valve, to interfere with its equilibrium. The valve is moved by means of a lever, and is opened and closed by a rocking motion of a steel spindle, which is covered with brass, ensuring the greatest possible durability.

THEY have a man in Bodie, who, some years ago, occupied an $800,000 marble front building, and did a large business in New York, and who is now working for a livelihood.

Harrison's Horse Hay Fork.

We illustrate herewith a horse hay fork patented, through the MINING AND SCIENTIFIC PRESS Patent Agency, by Edmund Harrison, of Hollister, California, who is an inventor also of a derrick and unloading uet. The fork is intended to lift large masses of hay or straw for the use of the threshing machine, or stacking or loading.

The tines are bent so as to grasp the load to the best advantage. These tines pass through the eyes upon the cross-bar, which keep them well apart and steady them. Above the cross-bar the tines are continued and brought together and strongly secured at one point, as shown. Strong eyes are secured to the outer ends of the bar and a triangular frame is formed of two other bars or arms, which are secured to these eyes at the ends of the bar so as to allow the fork to swing, and these arms meet in the middle above the head of the tines, forming a strong eye from which the whole is suspended.

It will be manifest that when suspended, the weight of the fork tines will cause the head to swing forward and allow any load to be discharged, unless it is confined in some manner. In order to do this, a hook is formed at the head of the fork, so that this hook just swings clear between the sides of the arms where they are bent to form the eye. A latch is pivoted to one of the arms and extended across the back of the other arm, so that when it is passed upward into the hook, it will prevent the fork from swinging forward, and as the latch rests across the small space between the arms, it will be seen that it will have great strength to resist the strain upon the fork.

Another great advantage possessed by this latch, is that it lies flat across the back of the fork, and does not project so as to catch or interfere with anything, if it is desired to hoist alongside of a mast or vertical post. In order to keep this latch up and make it catch on the hook, a spring is employed—secured to one of the arms—and this keeps the latch in position. A guiding staple on the opposite arm holds the latch in place, and limits the motion.

When it is desired to discharge the load, all that will be necessary is to pull the cord attached to an eye in the outer end of the latch. By this construction, the fork is made very strong, the tines being formed on a single piece each, with a liability to split, and it is very simple and cheap. The latching device is very strong, and by its position across the space in which the bead swings, it is capable of resisting a heavy load, and at the same time is entirely out of the way.

THE MANUFACTURE OF SILK.—This industry has been introduced finally in the form of a novelty to Californians, which may be seen at the corner of Stockton and Post streets, near Horticultural hall, where a Frenchman from Lyons is actually at work making silk. And the novelty consists in the exceedingly simple and modest, yet evidently practical and successful manner in which the industry has taken shape. He has a light and simply constructed hand-loom worked by treadles; and at the present time turning out lining silk. The simplicity and lightness of this French machinery at once attracts the eye. The wonder is that a single workman, with a simple and inexpensive machine, can compete successfully with wholesale manufacturers. Such we are assured not only is the fact, in the old world, but will prove to be likewise in California.

ALTITUDES OF AURORA AND BODIE.—Measurements recently made with a carefully adjusted aneroid barometer, show the town of Aurora, Esmeralda county, Nevada, to be 7,850 feet above sea level, and the town of Bodie, Mono county, Cal., 8,950 feet, or 1,100 higher. The top of Mount Davidson is 7,838 feet, and to persons traveling from Virginia City to Aurora it seems almost incredible that the latter place is as high as that peak.

GENERAL GRANT and party have left Suez for Bombay.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

Chilean Gravels and Gold Washings.

Editors Press:—The articles you published on "Hydraulic Mining," by Mr. Bowie, as also those by Mr. Hittel, on the "Dead Rivers," and others, are read and studied here with the greatest interest, since people here are beginning to be convinced that Chile is quite as rich as California in gold gravels; in fact, Chile is a

Duplicate of California

In its climate, geology, parallel mountain ranges, long line of sea coast and mineral wealth.

From the Chilean historian of the time of the conquest we gather that the Chilean Indians paid a yearly tribute of 1,400 pounds of gold to the Inca of Peru. Almagro, a Spanish officer, seized the tribute on its road to Cuzco, the residence of the Inca, and divided it amongst his soldiers. No doubt this gold induced him to march south to Chile, across the still dreaded desert of Atacama, to secure the mines whence this gold was produced. The tribute was cast into small bars of gold, marked with the Inca's stamp, and it was escorted to Peru by 400 horsemen, and there were rejoicings at the principal towns on the road. With the treasure there were nuggets worth $700 and $500.

The Indians of Coquimbo having revolted and killed the Spaniards there, those of Marga-Marga asked permission to retire from the mines, and the book of the municipality of Santiago, says as follows: Friday, 1st of November, 1549. The miners of Marga-Marga have written to this municipality that they desire to quit the mines, hearing what has passed at Coquimbo, but should they do so, the King of Spain would lose his royalty of one-fifth, which, valued according to the ordinance of March 3d, would be $64,973, and consequently the total extraction from Marga-Marga, would be some $300,000 yearly. Immediately after founding the capital of Chile at Santiago, the Spaniards commenced to work (A. D. 1549) the gold washings at Marga-Marga with Indians, and extracted such

Large Amounts of Gold

That it was weighed in the steelyard. Some Spaniards had as many as 600 Indians working for them, and as a result the gold was freely lavished on all sides.

At Quilacoya, the Governor Valdivia, employed from 10,000 to 15,000 Indians, and he pushed his conquests still further south and founded the "Seven Cities," in order to work the gold washings at Aranco, Augol, Canete, La Imperial, Valdivia, Osorno and Villarica. The Indians revolted and reconquered their Araucanian territory, and destroyed the Seven Cities, and still remain in possession of a great part of the southern territory. A foreigner now and then enters amongst the Indians, but he must beware lest he attempt to look for, and much less to work for gold. The traditions of their having been made to work for gold still exist.

There are abundant data to prove that the gold washings were

Worked on an Immense Scale

By the early Spaniards, as the records mention well-known places, a few of which I have visited; and since attention has been given to the subject, I may state that the work was done almost entirely in the river beds, and perhaps some ground sluicing, but the beaches are untouched.

Gold continued to be extracted by the pan and by ground sluicing till the discovery in California, which induced the greater part of the Chilean gold miners to go there, and since that period consequently our washings have been almost idle.

The idea prevalent here has been that the gold washings must be exhausted after 300 years working, and the jewelers who have latterly purchased the small quantities extracted these last 15 years, tell me they never had even the curiosity to visit the localities whence it was produced. It is true, however, as a rule that the miners refuse to state.

It has appeared impossible both to foreigners and natives, that such an

Extensive Gold Field

As Marga-Marga, 10 miles long by five miles wide, could exist almost at the outskirts of Valparaiso, the principal seaport of Chile, without their being aware of its value. I may add that there was no knowledge of such a mode as the hydraulic system to wash down the gravel, and to have stated that 1,000 tons of it could be washed daily was to be set down at once as an arrant liar. It was Paraff alone who was to do wonders and pay off the national debt of Chile.

It has taken three years continual writing, speaking, showing data to parties, and convincing some by taking them to see the gravel deposits, to induce a partial belief. We are on the right road at last, and people are commencing to prospect and bring samples from different quarters. H. A. Holcomb has contracted for some $80,000 the construction of a canal, the pipes, flumes, sluices, etc., necessary for the Nibliuto washings near Chillan, and John Simpson is in treaty for similar works at Caren. There is one

Point of Difference

Between the Chilean and Californian gold washings. Ours are located west of our coast range, and near the sea, at the outlet of some stream or river, and they extend from the Straits of Magellan, where Messrs. Hamilton & Shanklin worked, up to our most northern city, Copiapo, towards which, however, water is scarce. We do not appear to have what corresponds to your Blue lead at the foot of our snowy Cordilleras. Our coast range is traversed by numerous gold ledges which appear to have been the sources of our gold gravels. I should say our dead rivers must have run from Magellan straits to the north, and our marine current still runs towards the equator, both inversely to yours, but in a similar manner towards the equator. The dead rivers must have run to the west of our coast range since the gravels are deposited on that side, and not on the eastern fall or central valley; they account accordingly for the finding of our gravels all close to the coast, and in every case, I believe, traversed at right angles by the live streams running into the sea, which lay bare, and in many places show the bedrock upon which the gravel rests. These remarks refer to the central portion of Chile between Coquimbo and Concepcion.

In the South

Or Indian territory it would appear the gold is found right across from the foot of the Cordillera to the coast, but we have not heard of any deep gravels. Our river beds, as I said before, have been worked, where the sand or gravel was shallow and there was little water, but not in any places where the sand is deep and pumping or any machinery is required.

We are unfortunately separated from you by long distance, difference of language, and consequent ignorance of your mines and mining progress, and bad postal arrangements.

Mining Claims,

However, are easily and cheaply secured, and the law will protect you in holding your mines. Your capitalists and miners will find a new field where they will make fortunes as well as give new life to Chile, now suffering from a severe commercial crisis and from the low price of copper, to the mining of which all the energy and capital of the country has been devoted, and which delays the working of the gold washings and mines, for which latter there is not one single stamp mill yet erected. American eagles have been sold as high as 30, premium and drafts on the United States in proportion. There will be a demand for hydraulic mining engineers, and those with proper credentials will secure first-class positions. Miners who understand working monitors, erecting flumes, tail sluices and practical hydraulic mining will do well, as, also, those who understand river-bed workings on their own account will find plenty of room. The rest, as regards climate, security and government are satisfactory. Those who are not doing well in California and want a new field may come. They seem to consider almost any arrival from California as an authority, and one lately arrived gave an unfavorable opinion on a river-bed claim on the Marga-Marga stream, without knowing anything of or seeing the gravel deposits above the claim; surely in proportion to the richness and extent of the gravel benches, so will the river-bed claims be. Finally, therefore, we require capital and competent hydraulic and river-bed miners to give us new life, and I consider we can offer them good prospects. John P. Sewell.

Valparaiso, Nov. 22d, 1878.

Heat of Thermal Springs.

Editors Press:—The article in your issue of January 31st, under the caption of the "Heat of the Comstock," shows that Prof. Church's careful studies of the heat in the Comstock mines have rendered a service to science, by demonstrating that it is not due to radiation and conduction of the stores of heat of a once molten mass of contiguous rock.

Thoughtful students of the

Facts Developed by Mining

Have long seen that the more they are considered the more they appear incompatible with the generally received notions that all metamorphic rocks have been subjected to a semi-vitrifying heat, and all primitive and crystalline rocks have been in a state of *igneous fusion*. The same facts have driven into the background the formerly prevalent idea of the injection of quartz, molten quartz, as veins, into rock fissures. It may be said, even, that advanced students of nature begin to doubt whether the heat of all thermal springs and of volcanoes is derived from that hypothetical store of the molten interior of this once incandescent globe.

Convinced that another solution for these facts is required, I beg, through your columns, to add the following as

Correlative

To the conclusions of Prof. Church, given in the article above mentioned.

A mile south of the town of Cherry Creek, White Pine county, Nevada, on the sloping mesa, at the foot of the eastern slope of the Egan range, are San Rafael hot springs, belonging to the San Jose Mining Company, where, under my own observation, the out-flow of the water has been proven to be substantially uniform, but the temperature varying from 97° to 130° Fahr. This variation in temperature is at irregular intervals of time, for which there is no law of periodicity. The temperature of the water shows some sympathy with certain approaching changes in the weather, increasing on the approach of a southerly wind storm.

Upon these facts I make the following

Observations:

1. Since the out-flow of water is uniform and its temperature variable, the source of heat must be variable.

2. This seems probable only in one of two ways: Either the water must remain in contact with the heating surface longer at sometimes than at others, or this surface must be sometimes better than at others.

3. The steadiness of the outflow and the absence of periodicity in its changes of temperature, forbid the supposition that the water remains sometimes longer than others in contact with the heating surface of uniform temperature; by reason of a change of its route, or of intermittent storage.

4. We must, therefore, conclude that the temperature of the heating surface varies.

5. But if so, the heat cannot be derived from that great hypothetical reservoir of central heat; for reason and experience show that both radiation and conduction from this source must be so absolutely uniform as to make the temperature of the interior of the earth, at equal depths, all over the globe nearly equal. As an example, within my own observation at San Jose mines, Egan, Nevada (at the head of a tunnel 1,200 feet long and 450 feet below the surface, with its mouth open and hands and cars constantly going and coming, the outside air varying from 14° to 35° Fahr. below zero in winter, to 90° Fahr. in the shade in summer), the temperature never varied from 60° to 62° Fahr.

6. Central heat cannot, therefore, supply the heat that warms the waters of these springs, and we are driven to suppose that chemical, electro-chemical, or the heat of the magnetic tension must heat these waters to their varying temperature. That chemical decompositions and re-compositions are capable of producing any and all degrees of heat every educated person knows—every combustion from a candle to a conflagration is an illustration at once of the variability and intensity of chemical action. It is probable that careful observations on thermal springs, generally, would show variations of temperature in their waters, only to be accounted for by a variable source of heat, for which no cause seems so thoroughly adequate as the heat of chemical reactions.

7. But have we facts indicating such reactions in the crust of the cold and quiet earth?

Look at the changes of sedimentary into metamorphic rocks! Look at the crystalline, double, triple and multiple silicates called crystalline and primitive rocks! Chemical combinations cover the face of the globe. Who knows what stimulents to chemical reactions lie in great pressures, presence of water holding mineral solutions, accumulations of heat and vast thermo-electric earth currents, etc?

8. Is it not probable that hot springs and volcanoes derive their heat from great chemical reactions?

9. May not these reactions be converting sedimentary into metamorphic and crystalline rocks, as actively now as in past time?

10. If sedimentary rocks are the debris of primitive, why cannot and may not there be a chemical reorganization of these debris into crystalline rocks?

11. Is the conversion of sedimentary into metermorphic rocks anything more wonderful than the formation of artificial stone from its dusty elements? Or the change of one kind of metermorphic rock into another or into crystalline rocks more strange than the petrifaction of wood?

Let observers accumulate and publish facts about hot springs and metermorphisms found in mining explorations, and we shall obtain a key to nature's present mineralogical operations which will be valuable to science and to our mining interest. W. S. Rosecrans.

San Francisco, Cal., January 25th, 1879.

The Tuolumne Cave.—This cave has been explored for half a mile; and Gardner, the discoverer, thinks he has determined the extent of it to be over four miles. On the 1st of December, 1878, Garduer says he was engaged in working his placer claim, which is distant 300 feet from the entrance of the cave, when a squirrel perched itself upon a tree near by, and commenced to chatter and spit acorn chucks at him. He repaired to his cabin, armed himself with a double-barreled shot-gun, and fired seven rounds at his squirrelship—the seventh just as his little tormentor was disappearing in the dark recesses of this crevice in the ledge above his claim. Descending by ladder 10 feet, you reach the floor of an inclined archway, dipping at an angle of 35 degrees from 20 to 30 feet in hight, by 30 feet in width. Descending the incline, which is 100 feet in length, you reach the floor of the grand archway, from 40 to 60 feet in hight, varying in width from 20 to 30 feet, from which radiate scores of similar archways leading to spacious chambers. Lofty ceilings draped with brilliant stalactites glitter and sparkle in the light of a lamp like gem. The floors and wall of this subterraneous hall are entirely coated with stalagmites. The location is between the South and Main Stanislaus rivers, near their junction, and one mile northeast of the ancient and classical town of Pine Log.

Soluble Gold, Silver and Lead Combinations.

[Written for the Press by C. H. Aaron.]

Touching the lixiviation process, or processes, for there are several of them, it seems that one obstacle to their general adoption is the prevalence of gold, more or less, in our ores. It is true that Mr. Brookes, of Lower California, and other gentlemen, have stated that in treating the Mexican ores by the Patera or Kiss process more gold is got than formerly by amalgamation, but this process is not supposed to extract gold; and notwithstanding the rather unexpected fact, of which of course there is no question, it does not appear that it can be relied on when any considerable quantity of that metal is present.

I have as yet seen no explanation of the extraction of gold by this process.

In What Combination

Does it exist, and how is that combination produced? It cannot be the terchloride which is formed in Plattner's process, for that compound could not exist under the conditions I think; and if it could, it would all pass off in the wash water, or be reduced by the proto-salts of metals dissolved therein, which would make it insoluble in the leaching liquid. Neither can it be dissolved by persalts in the wash water, else it would again be lost.

There is, however, a certain compound of gold, chlorine and sodium, which it is possible to form in the furnace, at a low red heat, which is stable at that heat, and which, though insoluble in water, is rendered soluble by the aid of hyposulphites, but cannot be amalgamated. I cannot just now recollect my authority for these facts, but I remember that an attempt was made somewhere to adapt the principle to the working of gold ores, but I believe without much success, doubtless owing to the difficulty of getting all the gold into proper condition, though a furnace of special construction was used.

It has occurred to me that as the ores which Mr. Brookes is working contain a great quantity of base metals, including iron, which form in the furnace chlorides which are more or less volatile and unstable, it may be that, although the above mentioned compound of gold would not be produced at the high temperature used in finishing a charge of silver ore, yet the reaction may take place after the glowing charge is removed from the surface, and, as is usual, is allowed to lie in a pile for some time, during which the gradually cooling mass is permeated by vapors of salt, chlorine, volatile base metal chlorides, and possibly a little sulphuric acid.

If this is the true explanation, it may be worth the while of those who are engaged in treating ore by the Patera process, in those cases in which a little gold is present, to pay some attention to the matter, and so manage as to cause as much as possible of the gold to enter into this peculiar combination.

Soluble Silver Combinations.

Mr. Hoffman, in his interesting article on lixiviation by the Patera process, in your issue of Dec. 21st, says that the bath dissolves only that portion of the silver which is in the state of chloride. I must venture to say I think this a mistake.

I have heretofore published, in your columns, an account of some investigations of this point, which convinced me that the ordinary "chlorination test" made with sodium hyposulphite cannot be relied upon to determine the quantity of silver existing as chloride in the roasted ore, because a portion, often considerable, of silver is dissolved which is not chloride, and which, in my experiments, seemed to be a double or multiple sulphate of silver, lead, etc.

Moreover, I find that the hyposulphites, especially in hot solution, can extract a great quantity, as much as 80% of silver from unroasted ores in which it certainly does not exist as chloride.

The point may not be quite immaterial, for, though as Mr. Hoffman says, all the silver which can be extracted by the chlorination test can also be got in the larger operation; yet it is probable that the more perfectly the silver is chloridized the purer will be the resulting bullion, so that a test which is misleading in this respect is so far defective. Hot brine has the same inconvenience of dissolving compounds, other than chloride of silver, which may exist in roasted ores. Perhaps ammonia might answer better.

I cannot help thinking that the

"Lead Chloride"

Which Mr. Hoffman finds so difficult to extract with hot water may be the double sulphate (or whatever it is) which I found, and which is quite insoluble in hot water.

The compound mentioned is inconvenient in treating roasted ore in pans, as, though gradually reduced, it takes longer time, and the silver is contaminated by lead. Its formation may probably be prevented, in part, by the presence of plenty of available sulphur in the roasting ore.

Wire Netting for Protecting Crops.—It is stated by an English exchange that one Bristol firm, that of John Lysaght, sends no less than 1,000,000 yards of wire netting to Australia, where there is a growing demand for it, to protect the crops from the kangaroo and wallaby.

MECHANICAL PROGRESS.

Solidity in Iron Casting.

Great difficulty is experienced in the ordinary way of casting to get a uniformity in the mass and any near approach to perfect solidity. For some years past this difficulty has been obviated to a more or less extent by mechanical pressure. The possibility of doing this was very fully shown at the recent Paris exposition, by Mr. Whitworth, of Manchester, England, whose exhibit comprised an excellent collection of compact pressed castings, which, when compared with the unpressed ingots shown alongside, gave striking tendency of the utility and effect of mechanical compression in iron casting.

Since the introduction of mechanical pressure in casting, however, it has been discovered that a much better result in the same direction may be more readily obtained by chemical action. This chemical action consists in the deoxidizing action of manganese, silicon, etc., in the mass of the iron while in its molten state. This new process has quite recently been brought to an astonishing degree of perfection. This was fully shown, at the Paris exposition, by the French Terreuoire Company, and by other exhibits, both French and English. These exhibits proved most conclusively that compact castings, containing but small amounts of carbon, can be produced on a scale and to a degree of perfection hitherto unthought of, simply by a skillful use of deoxidants. Not only manganese and silicon can be successfully used, but tungsten and chromium can be employed to the same end.

Silicon has been found to be by far the most effective of these reagents; but it is accompanied with the disadvantage, that, when used in excess, it is more harmful to the quality of steel than that of either of the other substances used for producing the desired hardening results. For this reason manganese is preferred, and used in the form of ferro-manganese, or ferro-manganous silicide. Hitherto there has been much difficulty in obtaining such alloys; but at the present time these alloys can be produced in any desirable proportion up to 87% of manganese, a thing which, two years ago, was considered an utter impossibility. In addition to the value of this process of oxidation as a means for obtaining solid, compound castings, these same alloys are also employed for the purpose of deoxidizing mild steel, which can thus be brought down to any desirable degree of poverty in carbon, say, to five one-hundredths of a per cent. As already intimated, the technical progress which has placed this process within the range of ready practicability, is the discovery by which the compounds needed may be produced at a sufficiently cheap rate.

A New Test for Steel.

Although the mechanical and practical tests employed to ascertain the quality of steel undoubtedly offer the basis for a good estimate of the material, and valid conclusions may in many cases be drawn as to homogeneity from the appearance of the fracture, serious mistakes may be made in the latter course, because even close steely fracture cannot always be relied upon; nor is the fact that in manufacture the steel has passed through a liquid condition, a guarantee for its homogeneity. The question is, whether the particles of steel which in a state of rest are uniformly grouped, are so also when the material is subjected to stress. The molecular changes to which fibrous iron is subject under long-continued vibrations or concussions, are well known, and it is established that similar changes of structure, caused by molecular movement, occur with steel also, though not so frequently. The result of long-continued vibration of iron and steel, is a gradual decrease of cohesion. A means for ascertaining the degree of such a molecular change and its consequences, would naturally possess great practical importance.

Prof. Anton von Kerpely has recently read before the Hungarian Academy of Sciences, an important and interesting paper, in which he claims to have elaborated a simple means for attaining the desired end, a claim which he substantiates by the publication of the reproductions of a series of fractures of various grades of steel, obtained by widely differing processes of manufacture and under widely differing circumstances. His test consists of fracturing the sample when hot, and, in order to secure a uniform temperature below red, he has chosen the dark blue color as an indicator. The following is his method in carrying out this plan of fracturing when hot. The sample to be examined, is placed in a bath of lead, which is kept at low temperature in a graphite crucible. After 15 to 20 minutes, according to the thickness of the rod, it assumes the temperature of the bath. If a notch has not been made at the place where the fracture is to be effected, it can be easily done when the rod is hot. With a bath of low temperature the rod cools down too much by being placed on the anvil; in such a case it must be returned to the bath.

The best way to determine whether the sample rod has reached the proper color temperature, is to polish a portion with a file and notice the color of the brightened surface. If no color appears, or the blue disappears rapidly, the rod is too hot; but if any other color but blue remains constant for some time, the rod is too cold. As soon as the proper temperature has been struck the fracture must be made. Prof. Kerpely has made a long series of tests with steels from various processes of manufacture. His general conclusions from these are the following: Good crucible steel shows a peculiar behavior. Molecular change, though plainly discernible by the fine scaly structure, is trifling only when compared to results obtained with other grades. The fracture is almost smooth, and homogeneity seems to have been impaired but little, and it is only with the softest kinds of cast steel that the structure becomes somewhat more scaly in character. Bessemer steel of middling hardness showed quite a high degree of disturbance of the molecular structure, having a coarsely and deeply furrowed fracture, bearing some resemblance to wrought iron. Although it does not follow that all Bessemer steel will exhibit such characteristics, Prof. Kerpely believes that the fracture of the steel may be relied upon, in most cases, as an indicator in tracing the origin of a steel, and often in permitting conclusions as to the treatment it has undergone. The subject is one which certainly deserves experimental inquiry at the hands of American metallurgists and steel manufacturers.—*Iron Age.*

TRANSMITTING POWER BY ELECTRICITY.—Profs. Elihu Thomson and Edwin J. Houston have an important article in the journal of the Franklin Institute for January, concerning the practicability of the transmission of power to long distances by means of electricity. It has been stated by an eminent electrician that the thickness of the cable required to convey the current that could be produced by the power of Niagara would require more copper than exists in the enormous deposits in the Lake Superior region. Another statement estimates the cost of the cable at about $60 per lineal foot. Profs. Thomson and Houston on the contrary assert that it is possible, should it be deemed desirable, to convey the total power of Niagara a distance of 500 miles or more by copper cable not exceeding one-half of an inch in thickness. Stripped of its theoretical considerations, they say the important fact still remains, that with a cable of very limited size, an enormous quantity of power may be transferred to considerable distances. The burning of coal in the mines, and the conveyance of the power generated by the flow of rivers, may therefore be regarded as practicable, always, however, remembering that a loss of about 50% will be almost unavoidable.

TRANSMISSION OF HEAT BY STEEL PLATES.—Mr. John Collins, of the Bolton Iron and Steel Company, Pennsylvania, has been making some experiments on the relative heat-conducting power of iron and steel boiler plates. The apparatus used by him consisted of exactly similar plates of steel or iron 11¾ inches square, 23-100 of an inch thick, supported on glass legs, heated by a "Bunsen" burner consuming equal quantities of gas, maintained at constant pressure of two inches, and a basin three inches in diameter placed in center of plate, containing mercury in which a delicate thermometer was immersed. The temperature of the mercury was then raised from 20° C., to 160° C., and relative times noted. The average gain in time of steel over iron plates of equal thickness is 13%. When the relative thickness of the plates as used in boiler building is taken, this gives an average gain of about 20%. In steam boiler trials, where boilers are similar in all respects, say thickness and material, the actual gain in working 20 days of 12 hours each shows actual evaporative power of 20% in favor of steel. In another series of a similar nature by Stuckenholtz, the results gave 19.6% and 20.8% in favor of steel.

SILICIDE OF IRON.—Mr. Lawrence Smith called the attention of the Academie des Sciences, at the meeting of December 9th, to a remarkable specimen of silicide of iron. It was a piece of pig metal of about three kilogrammes weight, and with a brilliant surface which resisted almost all ordinary chemical agents. The color of the mass was almost the same as that of platinum, and its specific weight was almost 6.50. The result of the investigation to which Mr. Lawrence Smith submitted it is that this metallic mass is a silicuretted iron, remarkably rich in silicon, and that it is evidently the product of a blast furnace. The accidental discovery of this mass proves that there can be produced on a large scale, iron containing a much larger proportion of silicon than has ever been produced in the laboratory, and more than double that contained in the silico-ferro-manganese of the Terrenoire Company, which figured at the exposition, and which contained 10%.

IRON BUGGIES.—The introduction of iron buggies is now proposed. An inventor has constructed a vehicle which consists exclusively of iron and steel. For instance, in place of hickory spokes and oak felloes, he employs wrought-iron tubes and T iron; these tubes fit into the axle box at one end, and are rivcted to the T iron at the other. The first noticeable effect of the employment of iron for all parts, it is said, has been to add to the weight of the vehicle, this having accrued in spite of the thinness of the parts. The cost also has been enhanced, but for this the augmented strength and durability are regarded as a full equivalent. In appearance it is neat and light.

SCIENTIFIC PROGRESS.

Ultra-Gaseous Matter.

Mr. Lockyer's alleged discovery of the dissociation of the elements is not the only novel scientific announcement which has been made to the world during the past few months. Prof. William Crookes, of London, well known to the chemical world, has recently affirmed the probable existence of "a fourth state of matter—a new world—where the corpuscular theory of light holds good; but where light does not always move in a straight line."

It is well understood, and has been amply demonstrated, that the *three* states of matter—the solid, the liquid and the gaseous—though, widely different in their properties, are nevertheless only so many stages of physical continuity. The one passes into the other by insensible gradations, and with the third state it has heretofore been supposed that the possibilities of material change or condition were exhausted. But Mr. Crookes, in his crucial experiments, seems to have advanced another step, and has apparently demonstrated the existence of gases, so attenuated, and exhibiting properties so entirely novel, as to be fairly entitled to be considered ultra-gaseous, or matter in a *fourth* condition.

The means by which this remarkable result has been apparently demonstrated were fully described by Mr. Cronkes at the late December meeting of the British Royal Society. In his early experiments with electric discharges in vacuum tubes, the attention of Mr. Crookes was especially drawn to the dark space which appears around the negative pole of an ordinary vacuum tube when the spark of an inductive coil is passed through it. He has employed different gases and devised various arrangements for giving greater certainty to particular observations.

In order to more fully understand what Mr. Crookes has done, the reader should bear in mind that the physical properties of gases are due to their molecular condition—to the swing and impact of their molecules, and their average length of movement between collisions with one another. It is obvious that if the tenuity of gases is increased by exposing them in as perfect a vacuum as our best instruments can produce, the molecules may be so far separated from one another that their collisions must become much less frequent than under ordinary conditions, and might exhibit properties of an entirely novel character. That such is the fact, has been fully demonstrated by Mr. Crookes. In prosecuting his experiments, Mr. Crookes has arranged vessels capable of high exhaustion, and through these he passes induction discharges, sealing in terminals at either end. In this way he has studied the identity of the illumiuated lines of molecular pressure with the invisible molecular strain he has been for so many years observing. By introducing a cup-shaped fixed disc, which is made the negative pole, he has been able to show the focus of the lines of force. At very high exhaustion, the whole bulb becomes illuminated with greenish yellow, or, according to the glass, other colored phosphorescent light. This light will not turn a corner, but radiates from the negative pole in straight lines, casting sharply defined "shadows" of anything placed in its path. On the other hand, the ordinary luminous phenomena of vacuum tubes will pass along any amount of curves and angles. From a study of these "shadows" Mr. Crookes advances the theory that the induction spark actually illuminates the lines of molecular pressure, caused by the electrical excitement of the negative pole. He considers that the greenish yellow light is caused by the direct impact of the molecules on the surface of the glass. The "shadows" are not optical, but are molecular "shadows", only they are revealed by an ordinary illuminating effect.

As already intimated, his investigations began by a study of the dark space which surrounds the negative pole when an induction spark is passed through a highly attenuated gas. The width of this space was found to vary with the degree of exhaustion of the tube, with the kind of gas employed, with the temperature of the negative pole and with the intensity of the spark. The nature of the dark space Prof. Crookes interprets as follows:

"The thickness of the dark space is the measure of the mean length of the path between successive collisions of the molecules. The extra velocity, with which the molecules rebound from the excited pole, keeps back the more slowly-moving molecules which are advancing toward the pole. The fight occurs at the boundary of the dark space, where the luminous margin bears witness to the energy of the collisions of the molecules. When the exhaustion is sufficiently high for the mean length of the path between successive collisions to be greater than the distance between the electrode and the glass, the swiftly-rebounding molecules spend their force, in part or in whole, on the sides of the vessel, and the production of light is the consequence of this sudden arrest of velocity. When streams of molecular discharge are focused upon a strip of platinum wire or foil, the metal becomes not only luminous but highly heated by the severity of the bombardment; so, too, the molecular impact upon the side of the inclosing glass may be sufficient to make the spot too hot to be borne by the finger." Experiments had been made where the heat rose to the melting point of platinum.

By an ingenious device, the Professor had been able to bring a magnet to bear upon the stream of projected molecules, so that they were made plainly visible to the eye. Under the action of the magnet, the stream of molecules was likened, by the Professor, to a stream of cannon balls under the influence of gravitation. To use the Professor's own words:

"Comparing the free molecules to cannon balls, the magnetic pull to the earth's gravitation, and the electrical excitation of the negative pole to the explosion of the powder in the gun, the trajectory will be flat when no gravitation acts, and curved when under the influence of gravitation. It is, also, much curved when the balls pass through a dense resisting medium; it is less curved when the resisting medium gets rarer; and, as already shown, intensifying the induction spark, equivalent to increasing the charge of powder, gives greater initial velocity, and, therefore, flattens the trajectory. The parallelism is still closer when we compare the evolution of light, seen when the shot strikes the target with the phosphorescence on the glass screen from molecular impacts."

Applied to a stream of molecules the magnet twists the trajectory of the molecules round in a direction at an angle to their free path, and to a greater extent as they are nearer the magnet, the direction of the twist being that of the electric current passing round the electro-magnet. The two poles of the magnet twist the stream in opposite directions. The impact of the flying molecules raises the temperature of any body interposed to arrest their flight, just as the impact of a stream of cannon balls heats a resisting body arresting their flight.

The conclusions as to the existence of an "ultra-gaseous" state of matter arise from theoretical speculations as to the state in which it exists in these highly exhausted vessels. The modern idea of the gaseous state, as already intimated, is based upon the supposition that a given space contains millions of millions of molecules in rapid motion in all directions, each having millions of encounters with others in a second. In such a case, the length of the mean free path of the molecules is excessively small, as compared with the dimensions of the vessel containing it, and the properties which constitute the ordinary gaseous state of matter, and which depend upon constant collisions, are observed. By the great rarefaction which Mr. Crookes has, by years of experience, been now able to obtain, the free path of the molecules may be made *so long* that the hits in a second may be neglected in comparison with the misses, and the average molecule is allowed to obey its own motions or laws without interference; and if the mean free path is comparable to the dimensions of the vessel, the properties which constitute gaseity are reduced to a minimum, and the latter becomes exalted to an "ultra-gaseous" state. Then new and decided properties come into play.

Wood Pulp for Paper.

The scarcity of paper material has of late years led to quite a large employment of wood pulp as a mixture with other fibers in the manufacture of paper. Experience, however, is beginning to show that this addition to the usual paper stock is very prejudicial to the lasting quality of the material. Prof. Renleaux recently called attention to the subject in a lecture delivered at Leipsic, pointing out that, as the paper used in the German public offices is mainly composed of wood, the destruction from natural causes, of any important official records, may be expected. He limits their duration to about 15 years.

This reference is to writing paper, in which but a small quantity of wood is used. How much greater must be the loss and inconvenience in the case of printed books, into which a very large proportion of wood enters. According to Prof. Reuleaux's authority, all our libraries, if made up of paper so adulterated, will have to be renewed every 15 or 20 years, instead of lasting for hundreds of years, as is the case with paper made from the usual fibers.

MEAN DISTANCE OF WATER MOLECULES.—Herman Herwig concludes that no two molecular layers in water can be more than 1-86 of a millionth of a millimeter apart, and that the same is true with regard to the mean distances of adjacent molecular centers. Sir William Thomson had previously estimated the least value of the same distances at 0.05 millionths of a millimeter. These two estimates, one being less than four-fold the other, furnish satisfactory approximations to the true value.—*Ann. der Phys. u. Chem.*

ENORMOUS SUBMARINE PLANT.—Explorers have recently reported the discovery of an enormous submarine plant in the North Pacific ocean. It is known to botanists as the *Macrocistis pyritera*, is said to dwarf all vegetable products yet known by its prodigious proportions. It grows sometimes to such a size as to cover vast areas of sea-bed, one specimen having been discovered that occupied by measurement three square miles, while the stem was eight feet thick.

The Mining Share Market.

The mining stock markot remains in the fitful and spiritless but expoctant condition remarked upon at our last writing. This is especially the caso with Comstock shares, for which no sharp advance in prices is looked for until further ore developments shall bo mado at somo point along the great mother lode. This ovent many operators affect to believe will occur in the early futurs; some time in March or April at the latest, laying a foundation for the usual "spring rise." Without new ore finds of importance, it is generally conceded that higher prices for Comstock shares cannot be looked for; in the absence of these it will, in fact, be difficult to sustain present rates for any great length of timo. With but a single dividend-paying mine along the whols Comstock range, assessments, evon now paid grudgingly, will, hy and by, be declined altogether unless a hetter ore showing shall meantime be made. Let ths various managements bear tbis in mind and hasten to bring to light the honanzas that somo of them profess to have in reserve, and that all may hopo soon to uncover if indications are as favorable as they report. As enough snow is said to have fallen on the mountains to insure a pretty steady run of the mills on Carson river the coming season, thess Comstock companies need not restrain possihls ore developments through fear of insufficient facilities for reduction.

At the south end the Alta-Justice group of mines have of late shown a little more vitality, and it is expected that the Alta crosscuttings will shortly reveal a body of pay ore. The rigorous weathor, common to the winters of Bodie, has tended to curtail operations there, causing a corresponding torpor in tho shares of that district. All will, no doubt, be more lively with the advent of spring.

What are known as the "water stocks," being the shares of mines in close proximity to tho point where the Sutro tunnel intersects the Comstock lode, experienced a sharp advance towards the end of the week, in consequence of the settlement effected between Mr. Sutro and the mining companies; an event brought about through ths final agreement of the latter to pay the royalty as stipulated in the original agreement hetween these parties. While it is not probable that this adit will ever be much used for carrying out ores from the mines, nor yet for other purposes of transportation, it will undoubtedly bo of much seivico for relieving the mines of water, the great obstacle to deep exploration. From this time on it may he expected that these parties will act in harmony, and, abandoning the suits already instituted, dismiss the army of lawyers and cease further litigation.

Bullion Shipments.

Since our last issue, we have noticed the following bullion shipmente:

Indian Queen, Jan. 27th, $4,393.42; Tybo Con., Jan. 26th, $3,900.39; Paradise Valley, Jan. 29th, $3,814; Highbridge, Jan. 31st, $15,543; Tybo Con., Jan. 28th, $5,573.15; Hillside, Feb. 3d, $5,500; Christy Con., Fch. 1st, $6,475; Extra, Jan. 31st, $5,795; Northern Belle, Jan. 29th, $2,042.80; Grand Prize, Feb. 3d, $17,000; Navajo, Feb. 3d, $1,800; Tybo Con., Jan. 29th, $8,701.92.

A NEW MACHINE SHOP.—Messrs. Goss & Adams, formerly of Sacramsnto, have bought the machine shop at the old stand Nos. 114 and 116 Beale street, and are now prepared to do all classes of work. Mr. Goss was formerly of the firm of Goss & Lambert, proprietors of a foundry and machine shop in Sacramento. They began husiness there in 1852, and sold out in 1868 to the railroad company. Mr. Lamhert of the present firm, was foreman for the old one. They had as good a reputation as any in the Stats while they were in business, for doing all kinds of work, which reputation they propose to maintain in their new husiness. The works havs a complete outfit of lathes, planers and all nscessary tools for doing all classes of foundry and machine shop work. Ths present facilities are good, but tbey propose to amplify them as occasion demands.

G. W. SWAN & Co.'s Union Box Factory has received, through N. P. Gregory & Co., a 14x24 engine from the Buckeye Engine Co., of Salem, Ohio. It is a 96-horse power engine with automatic eut-off, and of a different style from any that has been previously brought to this coast.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

MINING NOTES.—*Ledger*, Feb. 1: On the Hercules the shaft is down 100 feet, and indications favor the development of a paying mine. It is supposed to be on tho mother lode. The ore looks well, carries a heavy percentage of sulphurets, with occasional specks of free gold visible. Ths Moore shaft is down 250 feet, with a ledge varying from five to seven feet in width. It is calculated to start tho mill early next week, preparatory to which quartz has beeu accumulating on the dump for soveral days. At tho Oneida sinking operations are through with. The running of drifts to strike the ore body is noxt in order. This will take from six weeks to two months to accomplish. In the meantime the mill will be kept operating with 20 stamps, oue-third of its capacity. At the Monterichard mine siuking is through with, and the mill has got steadily to work again. Tbo Kennedy company havs had a couple of men employed cleaning out their ditch—soms 20 miles in length. The work was done, not probably with a view to the early resumption of work at the mine, but to secure the property against jumpsrs. J. Millo has purchased the old State of Maine quartz mill of five stamps; has removed it to a mining claim near Middle Bar on the Mokclumne river, where he is having it put in trim for active operations.

PHŒNIX.—All the ore coming from this mine is good. They have been short of fuel for the mill, but by great exertions have managed to keep it running. All the employees have lately been paid in full aud business is lively.

BUTTE.

MINING OPERATIONS BEGAN.—*Record*, Jan. 31: Work was receutly commenced on the Modoc claim, located about two miles west of Bangor. They have a monitor in position and a pressure of 216 feet, which is secured by seven miles of ditch. The company also purchase a little water from the Forbstown ditch company. The opinion prevails that the bank uow being opened is situated on the rim-rock of ths famous Blue Lead mine. Should such prove to be the caso, the owners of this property have, most likely, a veritable bonanza.

BUTTE CREEK MINES.—*Record*, Feb. 1: John Allen bas struck good diggings at this locality; and having secured a plentiful supply of water from the Shephard ditch company, is washing away the top dirt from what appears to be an old river channel. The McIntrye claim is still paying handsomely. The Nichols and Longley claim is turning out well. We understand that the dirt is paying from three to five dollare a carload, and is easily worked.

CALAVERAS.

GRAVEL MINING.—*Chronicle*, Feb. 1: Tbe recent rains have furnished an abundance of water for mining purposes, and all the claims in this vicinity, for the first time this season, are now being worked to their fullest capacity. At the Duryea mine in Chile gulch, the system of operations has been changed from drifting to hydraulicking. A good deal of preliminary work has been doue iu getting the mine in proper shape—such as running tunnels for the accommodation of flumes, etc., for which wo fesl certain the proprietor will receive epeedy remuneration. At the Mammoth the gravel is looking bstter than ever before. A late partial clean-up yielded beyond all expectation. At the Bonanza things are progressing as usual. The miue is yielding handsomely, is systematically worked and admirahly managed. A large amount of water is used, and as the claim is well equipped and in proper shaps for working, every inch of it counts. Evans & McCann are still at work in their tunnel claim in Tunnel Ridge. They have not yet reached pay gravel, but are expecting to shortly. They are running what is known as the "old Sullivan tunnel," and are near the channel. The Eureka, located near the Calaveras river, is now in full blast. From 500 to 700 inches of water ars used. The Eureka is on this eide of the river, the water for hydraulicking being brought across the stream in iron pipss. We expect to be able to give a rousing report of the Eureka when a clean-up is made. Ground has heen broken for the great tunnel to be run by the Happy Valley and Blue Gravel Hydraulic Mining Co. But two msn are at work upon it at present, however, considerable preliminary work having to hs done hefore the enterprise can be commenced in good earnest. Work has been resumed at the Maison d' Sante hydraulic, one of the hest paying mines in tbie sectiou of the State. The Maison d' Sante paid largely last season, and we are informed that the prospects are favorahle for it doing as well this season. Tuesday, piping was commenced by the Happy Valley and Blue Gravel Co. They are washiug through a three-foot flume and using all the way from 500 to 1,000 inches of water. Work has heen begun in what was formerly known as the "Percival claim." The rains have also set men at work in placer diggings, and the mining interest is flourishing in all directions.

DEL NORTE.

MINING ON ROGUE RIVER.—Crescent City *Courier*, Jau. 22: There is more or less mining going on along the river. It ie a hard matter to ascertain the amount of gold taken out during tho year, but it is evident that the miners make it pay or they would not remain so long as some have. Very fino prospects have been fouud high up on tho benches, beth on Rogue and Illinois rivers. On the Illinois river it would pay a company with capital to bring in a ditch and work the benches, which are one above the nther, and prospect well down to the bed of the river. Six or seven miles of a ditch will bring a sufficient snpply of water. Ths gold is coarse. Experienced miners state if water could be brought on the grounds that men could make about four dollars por day.

MONO

WEEKLY MINING REVIEW.—Bodie *Standard*, Feb. 1: The past week has beon remarkable mostly for one of Bodio's sovere snow storms, which has covered the ground to a depth of a few inches. Our leading mines being under cover, work in exploring has not been retarded in any material degree, hut has been continuously pushed ahead with vigor and persistence. Tho wisdom of crecting substantial buildings over shafts and machinery is now makiug itself mauifest, and the result is a subject for congratulation. During the week the Standard and Bodie mines have been producing their usual quota of ore, that from the former being of higher grade than worked last month, much of it bsing taken from the new strike mads while crosscutting. Tbe Bulwer has bsen shipping ors to the Bodie mill, which it ie expected will start up this week. With three dividend-paying mines we ean open the spring seasou with cheering prospects and the product from tbe ores worked will effectually silencs the Emperor Norton style of bears now so fashionable on Pine strect. The owners of the Lucky Rodge, a location on the western slope of Bodie bluff, have honded their property to Howard Hastings of the Mono County Bank, and there is scarcely a doubt that a sale will bs made before 30 days. The mine in question has produced some fabulously rich rock, one piece taken from near the surface having assayed nearly $40,000 to the ton. The Con. Pacific, South Bulwer, Goodshaw, Mono, Champion, South Bodie, South Standard, Red Cloud, Booker, aud, in fact, every mine having facilities for working to a depth are all looking promising in the extreme, and another month's work must bring to the front many magnificent properties which will bs self-sustaining. Our winter must necessarily be of short duration, as the seasou is so far advanced that the sun's rays will melt the enows which would otherwise lay long npon the ground. We anticipate that next March our winter will be about over, and that the influx of speculators and mining men will then commence. Taking everything into consideration we can see no good reason to donbt the fact that Bodie will within three months be the leading attraction of tho mining world, and that she will base her claims to the first place on pure merit there cau be no doubt iu the mind of any unprejudiced person.

NEED OF WATER.—The question of a sufficient supply of water for the mines and the consumption of the people will become a serious question during the next season. The light fall of snow for this section, and the consequent drying up of wells in the summer months, will be a serious matter before the year is out. At the present tims there ars a few of our mines which supply water sufficiently (if used) for their own uses, but tbe great majority of properties are ohliged to have their water supply conveyed to them by means of barrsls loaded on teams. The present open winter has rendered it possible for teams to keep their customers supplied with water, hut at a great expense to consumers. We have heard several schemes broached, having in view the supplying of this nccessary article to our mines and town, hut, as yet, know of no actual live measures having heen adopted or consummated. There is money iu this scheme for parties having capital, and we have no doubt that some clear-headed speculators will make succcssful what now seems chimerical and uncertain. There's money in it, and consequently it is only necessary to interest the proper parties to make the matter a complete success.

NEVADA.

WATER STILL SCARCE.—*Transcript*, Feb. 2: During the progress of the last heavy storm there was a head of 7,500 inches of water in the South Yuba Canal Co.'s main ditch. At one time last week the amount had diminished to 1,500 inches, on account of the small streams from which the supply is dsrived freezing up during the cold nights that have prevailed for some time. At present there is only a head of 2,700 inches in the ditch. It is earnestly hoped that a warm storm will soon set in and increase the supply, as the hydraulic mining interests are suffering considerably now. There are hut 300 inches of water iu Deer creek now, whereas that channsl ordinarily contains 2,500 at this season of the year. The Manzanita mine is obliged to remain idle a good share of the time on account of the scarcity of water, and the Blue Tent claims aro doing nothing to speak of. The North Bloomfield manages to kesp going on a limited scale.

TRIBUTE ROCK AT GRASS VALLEY.—The *Union* says there is now no difficulty in Grass Valley district in making contracts with companies of working miners to take out quartz on trihute, from mines which give a rcasonable assurance that the rock will pay fair wages. At the present time a great deal of work is being done on this plan, and while men do not in every instance make good wages, numbers have been fortunate enough to make as much as four and five dollars or mors per day. It is only within the past year or two that work has bseu done on this plau thers to any extent, but it seems to be coming into gsnsral operation, and now ths majority of tho mines of the district havo tribute companies at work, and even some of ths operations of prospecting companies are carrried on by this system. So far it has generally been found to work advantagsously to both mine owner and ths miner, as it has lessened the cash outlays of ths first and given a great deal of employment to ths latter, who might not otherwiss havs found steady employment at the current rato of wages.

HUNT'S HILL.—John McAllis has started operations at his mines. He is at present using 500 inches of water, all that is running in the Cascads ditch at present. Ths Florencs company are all ready to wash as soon as water ean be obtained. Work will commencs in ths Sargent & Jacobs claim as soon as their ditch is thawed out, and from present appearances they will not be obligsd to wait long.

PLACER.

ABOUT OPHIR.—*Argus*, Feb. 1: The hauling of quartz from the St. Patrick mine to the Crater mill was resumed on Weduesday. The mill will begin crushing again next week. An excellent quality of rock is being taken out. Quite a number of men are prospecting on Duncan hill, back of the Stone house.

NEVADA HILL.—*Herald*, Feb. 1: This mine yielde good ore, but is not now being worked in consequence of an excess of water, from which it cannot be freed with the present iusufficient machinery. As soon as the weather will permit, work will be prosecuted here in a vigoroue and efficient way. A. O. Bell, the discoverer of this mine, is busy prospecting in the same locality, fully confident that he will strike another bonanza, and we sincerely hope he will succeed. Mr. Bell is one of those kind of men who allows his money to circulate frsely; giving employment to the unemployed and thereby assisting the industrious poor. Such men are an advantage to a community.

SNOW.—They have had two feet of snow on the Forrest Hill Divide, affording good sleighing—the best bad there for 20 years.

TUOLUMNE.

MINING ITEMS.—*Independent*, Feb. 1: At Union hill Thos. Adame etruck a rich streak in his quartz claim last week and in two pans took out $254, with a good prospect for getting more. The five-stamp mill on the Keltz mine started up on Friday for the first time. The mill is large enough to accommodate five more stamps, which in all probability will be added in the spring, The Draper struck a good chute in the upper level going north, last week. Nine-incb vein, showing heavy lead sulpburets. Ben Soulsby has a good vein near Soulsbyville, supposed to be the north extension of the Soulsbyville mine. The Golden Rock mine, above Garrete, is now iu full hlast, water being abundant. About eight or nine men are employed, running two giants. The ditch has heen kept open all winter, in spite of the forces of the Storm King. The prospects are good, the stream being set against the gravel banks, 84 feet high. Wheu they get to the deepest part, the bank will be somo 150 feet high. The great difficulty now is, to find just where the channel really is. This will be better developed when a large amount of the top is stripped off. Tho Managing Agent, C. Dorsey, Esq., intends to test the mine thorougbly, hefore going into the extensivo operations contemplated, if everything proves as anticipated.

SIERRA.

MINING ITEMS.—*Mountain Messenger*, Feb. 1: The Michigan claims, near Gibsonville, owned by Clough & Lowell, are again paying well, or rather, the miners are taking out "hig dirt." A piece weighing four dollars was picked out of the dirt by one of the workmen the other day. Work at the Pliocene shaft has been etopped for the winter at lsast. So much water was encountered that it was found impossible, with tho present machinery, to make any progress. What course tbo company will pursue we are unahle to say.

NEVADA.

Our usual wsekly summary of news from the Comstock mines has failed to reach us, and ws are thereforo compelled to go to press without it.

BELMONT DISTRICT.

HIGHBRIDGE.—*Courier*, Feb. 1: No change in the mine of note. Are extracting the usual amount of ore. Have added five more stamps to the battery, which now crushes as much ore as the balance of the mill can handle. Will ship to-morrow bullion valued at $15,543.51. Total shipment for the mouth, $43,452. After starting up the mill, some two months ago, it was found that altorations in the machinery were necessary, wbich prevented making progress in the crushing of the ores that otherwise would have heen the case. The changes and improvemeuts found necessary, are now about all completed, and hereafter the company will be enabled to increase the production of hullion. Cousidering the many difficulties that have had to be contended with, the production for the mouth of January is very respsctable in amount.

TYBO CON.—Shipped to the 25th ult., on January account, $47,656.12. Ths furnaces have both bsen run down, cut out and re-linsd the past week. The work was done rapidly, No. 1 being closed only 18, and No. 2, 19 hours. There ars no changes of importance to nots in

Continued on page 92.

Cosmic Meteorology.—No. 3.

[Written for the PRESS by SAMUEL PURNELL.]

Although I have not seen it mentioned elsewhere, I would call attention to the suggestive fact that the sun-spot cycle of 11.11 years is just one-third of the alleged meteoric period of 33.33 years, which would seem to point to a connection, more or less close, between the two cycles. How they are or can be connected, I have not had the opportunity of even attempting to ascertain, and it is perhaps idle to speculate.

I would also call attention to the fact that the times of maximum and minimum of sun-spots appear to have a definite relation to the

Prevalence of Plagues

And pestileuces, particularly of cholera and yellow fever, each seeming to rage most malignantly during years of the minimum groups. As it is my intention to treat this brauch of the subject in a more thorough manner hereafter, I will only add that cholera prevailed extensively from 1841 to 1843, 1853 to 1855, 1865 to 1867, in each of which periods was a year of a minimum group; and the yellow fever appeared with great virulence, in the United States, in 1798, 1853, 1867, and 1878, all of which were minimum sun-spot years except 1853, and that was very near the year. That the theory of the prevalence or ahsence of sun-spots, as affecting diseases, can have some reasonahle foundation, will probably be clearer after the cause of the spots is duly cousidered; because, as startling as the thought may be, if it is known that a more or less active condition of the surface of the sun can cause such changes in the physical motions and conditions of our globe, it is reasonahle to assume that life, as manifested in man and animals, can be and is similarly affected.

A Difficulty

That meets the studeut in trying to solve the suu-epot problem consists in the fact that there is yet among astronomers no definite plan of recording sun-spot ohservations. Not until 1826 were they regularly observed, and for many years afterward only the number of new spots or new groups was recorded. Of late years the area of the spots has also been measured. Yet there can he little douht that several elements in the stating of the problem are wanting. Besides, the first appearance, the area, and the duration of a spot, there should evidently be noted in addition, its persistence, intensity, and motion; the condition of the prominences and the photosphere, the position of the planets, and all other accessible solar phenomena. The spots are probahly not originated hy the sun itself, hut by outer and perhaps unknown influenccs, and these are only to be learned, and the sun-spot problem mastered by a study not only of the spots but of all the accompanying celestial changes; and for this purpose the eun's surface is a chart indicative of these changes.

Introductory to the following tahle, principally compiled by Lockyer and Huuter, it will be well to premise that the actual sun-spot

Maximum Years

During this century have heen, in round numbers, 1870, 1860, 1848, 1837, 1829, 1816, 1804; and the minimum years, 1878, 1867, 1856, 1843, 1833, 1823, 1811:

	Minimum group of the 11-years cycle.	Intermediate group of the 11-years cycle.	Maximum group of the 11-years cycle.
Wolf's mean relative sun-spot number	12.6	43.55	76.80
Diurnal inequality of magnetic declination, 1813 to 1871, Prof. Stewart.	6.74	7.72	9.45
Electric displays, auroras observed, Prof. Loomis	23.	42.	55.
Number of cyclones of Indian ocean, 1856 to 1867, Dr. Meldrum	7.33	8.25	13.25
Relative area of cyclones of Indian ocean, 1856 to 1867, Dr. Meldrum	2.10	3.39	9.21
Number of hurricanes of West Indies, 1810 to 1873, Poey	2.53	2.72	4.25
Percentage of losses on registered vessels of Great Britain, 1856 to 1876, Jeula and Hunter	11.25	11.44	12.52
Madras rainfall, total average, 1813 to 1876, Hunter	40.39	49.07	53.50
Average annual rainfall of Bombay, 1817 to 1876, Hunter	68.78	71.89	75.28
Average annual rainfall at Cape of Good Hope, 1842 to 1870, Hunter and Stone	21.05	23.59	27.95
Madras famine (causing drouths), 1812 to 1876, Hunter	5	1	0
Brazil, drouths	13	10	7
Derby, floods	2	4	6
Relative annual amount of atmospheric ozone, 1850 to 1869, Moffat	1.5	1.7	2.1

In close connection with the sun-spots are the

Strange Forms

That are seen upou the edge of the sun, exquisite in color, fantastic beyoud description in outline, and of stupendous magnitude. These are the so-called promineuces, or red flames. They were formerly visible only during solar eclipses, but now may he looked upon duriug any clear day. At one time a dozen may be seen around the edge of the sun, some of them 100,000 miles high, at other times there is scarcely the most feeble indication of this form of solar activity. Like the solar-spots the prominences wax and wane, simultaneously with, aud proportionately in size and intensity to the sun-spots. They are usually considered to be phenomena of eruption, hut their nature is little understood. This being a year of extreme minimum of sun-spots, we should expect the prominences to be much below the average, and accordingly the royal observatory of England announces in its report for the year ending May 2d, 1878, that "all the observations go to show that the solar prominences have been few in number and insignificant in size for many months."

Another interesting phenomena exhibited by the sun is the

Corona,

The beautiful crown of light seen around the moon during the moments of total solar eclipse. It was formerly thought to be due to the atmosphere of the moon, but is now recognised as a true solar appendage. Its cause and constitution are at present a matter of speculation. Mr. Lockyer holds that it shines hy light reflected from the sun by a cloud of meteors surrounding that luminary, and which are probably arranged around it elliptically; the corona itself, being mainly composed of violent uprushes of gas from the sun's interior in spot maximum years. In spot minimum years the corona contains uo gas. In this connection it may be remarked that Mr. Lockyer regards sun-spots as down-rushes of gas, and as showing evidence of a return convection current. When a year of maximum sun-spots occurs, or *vice versa*, and a total solar eclipse also occurs, it is seen that

The Corona is Varied

In color, size and intensity correspondingly with the spots, and the proof is clear that they are intimately connected, and perhaps both are due to the same celestial disturbance. Could the corona be examined at pleasure, its periodicity would be speedily shown, yet at eclipses its varying conditions have been especially remarked. According to Mr. R. A. Proctor, recent eclipses indicate that during years when sun-spots are numerous, the corona presents an appearance entirely different from that of last July, when the sun was almost free from spots. During the eclipse of 1871, a year in the maximum group, the corona extended at least 250,000 miles from the sun, while in July last, it reached a hight only of some 70,000 miles; in the former year it possessed a very complicated structure and was pink, while in the latter it was pearly white. The year 1705 was a year of maximum sun-spots, the corona duriug the eclipse of the following year was very extensive. The year 1717 was a maximum year; the eclipse of 1715 sbowed a maximum corona. Iu 1724, the corona was small; the ycar 1723 was one of minimum disturbance; the same may be said of the corona of 1766, and the spots of the same year, and of a number of eclipses since. The principal comparisons of the corona with the sun-spots are based, on the finely observed solar eclipses of 1871 and 1878. The corona seen last July, led to the inference that the gaseous matter which was present in 1871 was either entirely absent or greatly reduced in quantity. It was very much less brilliant thau usual, and smaller, a few prominences were seen, and several bright streamers. In 1871, there were many spots, many prominences, many magnetic storms and auroras, excess of rainfall, no famines, and a large and brilliant corona. This year there are few spots, prominences are rare, the magnets were scarcely ever so quiet, famines abound, and a small corona. Mr. Lockyer says that at present the

Solar Energy

Has run down: with the reduction of spots and prominences during the last four years, the terrestrial magnetism has been less energetic than for the preceding 40 years, while at both ends of this period, there have been famines in India and China. The present quiet position of the sun is worthy of minute study. The absence of lines from the coronal spectrum shows a great reduction in the temperature of the sun, and such a marked change in it should produce a corresponding change in the earth, as the condition of the earth sympathizes with the condition of the sun.

What is the Sun?

What a correct answer to this question would be, nobody knows. A few particulars, the least important, perhaps, are thought to be known of the constitution of some of its portions and of some of its powers, hut of it integrally and materially, human knowledge is scant, and, possihly, what is thought to be estahlished truth is really hut error. When almost every philosophical astronomer is of a different opinion from his fellows relative to the nature of the sun, some claiming that the sun is hot and some that it is cold, it is easily perceived that exact knowledge concerning it has not yet heen attained. But, to state the most ohvious conclusions, if the parallax has heen correctly determined, the distance of the sun is some 93,000,000 miles, its diameter some 850,000 miles, its volume is some 1,250,000 times that of the earth, and at an equal distance it would exert 315,000 times as much force ou a body as would the earth; its specific gravity is thougbt to he 1.367, or about one-quarter that of the earth; the weight of a body on its surface would be about 27.36 times greater than on the earth; its rotation on its axis is accomplished in about 25.34 terrestrial days; it is moving through space at about five miles per second; its daily rotation is 14° 18'. Mr. Lockyer says the sun is now generally considered to be a

Huge Incandescent Globe,

The very coolest part of which is glowing with a heat which transcends all our earthly fires; its heat is not thought to be due to combustion, as in our fires, hut to the vivid incandescence of each particle, brought about hy the original contraction of the vaporous globe, or by causes even more remote and unknown.

The Earth's

Velocity around the sun is 18.2 miles per second; the volume of the earth is so small that it intercepts less than two-millionth of the sun's radiated energy. Theoretically, the maximum limit of the atmosphere is about 21,000 miles, at which point the centrifugal force is equal to the weight of the air; the minimum hight is about 30 miles, or about the 130th part of the earth's radius, the actual hight of the sensible atmosphere may be 200 miles, the entire weight of the air is about 1-1,100,000 of the weight of the earth. The weight of water is 770 times that of air. Tropical evaporatien is supposed to amount to at least 16 feet of water, of which about six feet fall in the same region, and about ten feet are transported toward the poles; the surface from which the evaporation takes place may be estimated at 70,000,000 geographical miles, and from this it will be seen that the depth of 10 feet of water represeuts a volume equal to 25,000 billions of cubic feet (25x10.15), transported through the atmosphere by the power of the sun's rays.

The above figures will give the uninitiated some idea of the earth and its atmosphere, the volume of the sun and its powers, as affecting the rainfall and sun-spot problem. A brief account of

Various Opinions

Of the sun-spots, their probable cause, and how that condition of the sun and planets of which they are a measure, affects our earth, in the forms already mentioned, will conclude this part of the subject.

While this subject was formerly. and is now beset by the impossibility of getting accurate accounts of the solar spots, the future studeut of cosmic meteorology will possess sound data upon which to erect his dictum and decision. Of late years a minute study of the sun-epots has been made a part of regular observatory work, and in a few years more, most interesting facts may be published. So far the observations and speculations of two centuries have not sufficed to determine the true character of the spots. The most fantastic notions of them have been indulged. The students of the Aristotleian philosophy denied the possihility of their existence, alleging that it is impossible that the eye of the universe should suffer from ophthalmia. It has been variously thought that sun-spots were only apparent not real; that they were in our atmosphere or our glasses; that they were wandering cosmical hodies hetween the earth and the sun; that they were caused hy meteoric streams upon the snn; that they were great yawning chasms in the outer atmosphere of the sun; that they were solid parts of the sun exposed from time to time by the ebb and flow of a liquid, fiery and transparent sea; that they were parts of a cool and habitable globe. The hest modern opinion seems to be that they are really openings in the sun's atmosphere of a cyclonic nature, through which gas pours in and out. According to Father Secchi, they are "solutions of continuity in the stratum of mists or luminous vapors which form the photosphere."

The spots are confined generally to

Two Definite Zones,

Extending about 35° on each side of the solar equator; an intermediate zone to a distance of some 8° on either side of the equator being usually free from spots. Tints of red within the spots have been noticed, and are supposed to he part of the chromosphere which surrounds the whole globe of the sun. Spots have various motions—rotatory and rectilinear; change in figure or wholly disappear, often in a single moment. The motion of a spot across the sun's surface from west to east has heen observed to have a velocity of 600 yards per second. They vary incessantly in form and position, remaiuing most frequently upon the suu during one or two of his rotations. They are not of uniform brightness, but are commonly surrounded by a fringe less dark than the central part. Their size varies; the least spot that can he perceived with the telescope must have an area of at least 50,000 miles; in 1828 a spot appeared which was equal to four times the earth's diameter; in 1839 appeared one of seven times, and in 1859 appeared one of 18 times the diameter of the earth. But whatever sun-spots may he, or whatever their cause, the scientific world is now sure of

One Leading Fact,

Which is that the energies at work upon the sun are not constant. At times the spots are so enormous as to he visible to the naked eye, at other times the sun is apparently spotless. At times glowing vapors rush up from its bowels with great persistence, at other times they are invisible for months; and when there is the greatest number of up-rushes of heated matter from below, there is the greatest number of spots and prominences. According to Mr. Lockyer, the spots may be taken as a rough index of solar energy, just as the rainfall may he taken as a convenient indication of terrestrial climate. They are an index but not the cause or complete measure of solar energy, and their apparent absence indicates a reduction, not a cessation of solar energy—the percentage of which is unknown.

Speculations.

Prof. Loomis believed that a sun-spot is the result of a disturbance on the sun's surface, with some emanation from the sun that is almost instantly felt upon the earth. Father Secchi remarked that the variation of the sun's activity may well be communicated to the earth, either hy means of heat or some other channel as yet unknown; such, for instance, as by electro-dynamic action, thus producing upon our earth meteorological or electric phenomena. Becqueral maintained that the origin of atmospheric electricity is the sun, and that there can he no other complete explanation of the enormous quantity diffused in the atmosphere; and he was also of the opinion tbe the positive electricity of the sun is carried through planetary space by hydrogen gas.

What the substance or force is by which the energy of the sun, with all its quick variations, is almost instantaneously transmitted to the earth, affecting the entire globe so powerfully, is yet a matter of speculation; but it seems reasonable to assume that it must be an etheric force of a nature similar to electricity, but finer and of more poteucy.

The Cone-bearers, or Evergreen Trees of California.—No. 3.

[Written for the PRESS by J. G. LEMMON.]

Spruce Family.

Our last paper closed with the enumeration of the pines of California, composing the first genue of the four large genera belonging to the tribe *Abietinæ*.

The other genera are *Picea* (from which a small genus, *Tsuga*, has lately been seperated), *Abies*, and *Larix*, commonly called epruce, fir, and tamarack, the two first of which, for reasons following, we will consider together. The flowers of these genera are similar to the first genus, *Pinus*, to which the older botanists referred them, calling them all pines, but subsequently they were separated under the name of *Picea*. Soon after a part of the species was erected into another genus and called *Abies*. Other botanists extended the name *Abies* over the whole group, and *vice versa*. Thus the two names, *Picea* and *Abies*, have heen much interchanged, and often one of them dropped entirely, causing great

Confusion from Misnaming.

This confusion extended to the common names, spruce and fir, as well, and still continues to thie day.

The consolidation of this group into one genus was based upon the fact that they have several characters in common, to wit: cone-scalee flat, not thickened at apex, nor spurred; leavee single, short, scattered, not sheathed at base. Their separation into two (and finally, lately, into three) genera, is hased upon differences in the characters of their fruit—by most authorities regarded as very important—to wit: Spruce cones depend from any of the branches, and fall off, entire, at maturity, like the pine; fir cones stand erect upon the upper limbs and fall to pieces at maturity, leaviug the core persistent.

Ae stated, much confusion and controversy has been connected with this large and interesting group of trees; and intelligent lumbermen, as well as scientists, are found calling species by opposite names, according as they follow different authors, but the matter has been recently settled as above, as well as by microscopic examinations, and we, who live among the noble trees, ought to avail ourselves of the facts, study the distinctions, get them well fixed in our minds—then hereafter, eet a proper example, thus clearing away the confusion.

Engelmann's Dictum.

Dr. George Engelmann, of St Louis, the closest student of our trees in America, has just published an exhaustive description of the American firs, in which he says: "I follow Link in his name, definition and limitation of the genus *Abies*, which seems to be a very natural one, comprising the silver and balsam firs."

The synonym *Picea* is the older name, and enjoye the Linnæan prestige, hut is contrary to classical (see Pliny and othere), and to philological authority. The name *Abies* is generally adopted in Europe, while *Picea*, heretofore priucipally used in England, is now being abandoned.

Picea is the pitch tree, and properly designates the spruces. Tournefort, the elder De Candolle, Gray and others, comprise under the name *Abies* hoth the spruces and firs; "hut," the Doctor declares emphatically, "the generic distinctions hetween them are abundant, and hased on floral and fruit characters, as well as upon the leaf anatomy."

Spruce Family.

The spruces are distinguished from the firs by their depending coues growing from any of the limbs, with persistent scales and hracts, and, generally, by their scattered limhs and leaves; also hy microscopic anatomy, as shown hy Eugelmann. They comprise two genera, *Picea* and *Tsuga* forming the second and third genera of the *Abietinæ*, as stated, differing from each other hy hut few characters detected at a distance; five species in California.

2d. genus, *Picea*, from *pix*, "pitch." The true spruce. Leaves four-sided, and generally scattered all round the long twigs, leaving, when they fall, the foot-stalk, persistent, ligneous and prominent. Bracts concealed heneath the cone-scales.

1. *Picea Pattoniana*, (*Abies Williamsoni* of English authors). "Silver spruce" of California. Grows sparsely on the peaks of the Cascades in Oregon and in the Sierra of California (near Webber and Tahoe lakes, and on Lassen,

Stanford and Tellae peaks). It is an exceedingly graceful tree, tall and tapering, with longest limbs below, all starting out downward from the trunk, thsn outward, lastly upward. Cones iu clusters at the ends of branches; purple; small; two to three inchos long; ollliptic; bracts short, concealed by the few concave, close scales, but half opening at maturity.

2. *Picea Sitchensss, Bony.* "Menzies' spruce," of Oregon and upper California. A graceful trce, 80 to 120 feet high, with long pendant twigs; timber yellow, tough; hence prized for shipbuilding; cones elliptic, two and three inches loug; leaves on lower limbs often 2-ranked.

3. *Picea Mertensiana*, Lindl. "Hsmlock spruce" of Oregon and upper California, coast; 100 to 150 feet high. "The uorthern forms," according to Dr. Kellogg, "densely foliaged, but exceedingly graceful in their arching branches; the southern with perfectly horizontal spray, airy and gauzy, giving an effect beautiful beyond description." Timber white, soft, worthless; cones very small, one-half to one inch long; ovate; leaves generally 2-ranked.

Certaiu species of the genus under consideration have lately heen separated from the preceding and named *Tsuga*, the "false spruce." Leaves flat, uot four-sided, and generally in two ranks on opposite sides of twigs, falliug off entiro, leaving a round scar on the bark. Bracts, oxserted.

4. *Tsuga Douglasii*, Lindl. "Douglas spruce." "Black spruce" of the Rocky mountaius, and of the California coast and Sierra ranges. A common and often immense tree, 200 to 350 feet high, with a rongh, black barked trunk 8 to 15 feet iu diameter. Timber soft but stroug, composing the great lumber wealth of Oregon and Washington; cones ovate, three inches long; hracts much exserted, three-parted; leaves light green, arranged iu spirals around the hangiug twigs.

5. *Tsuga macrocarpa*, Torr., or *Tsuga Douglasii*, variety, *macrocarpa*, Vasey, the "big-coned spruce" of the San Bernardino mountains. A rare tree, differing from the typical Douglas spruce in its smaller size, guarly appearance and the great size and quantity of its cones, 8 to 11 inches long, and lying a foot deep beneath the trees.

(To be Continued.)

The Engineer.

A Review of the Past Year.

In engineering, the year just past can scarcely be said to have afforded much matter of iuterest; for beyond the progress made upon a number of important works of improvement, aud the completion of a few others, there is but little to notice. The only specially novel engineering undertaking to record is the successful transfer of the Cleopatra Obelisk from Egypt to England—to its present site on the Thames embankment in London. The engineering skill is displayed in this work by the contractors has been highly praised by the leading professional journals of England, and appears to he deserved. The practical completion of the great Sutro tunnol was by all odds the most interesting and important performance in this department of the United States during the year. The improvements works at the mouth of the Mississippi do not appear to realize the sanguine expectations and predictions of their projector to the extent that his many warm advocates had hoped. It would, bowever, be premature to pass judgment at this time upon the merits of the controversy that is known to exist between Capt. Eads and the U. S. Engineering dcpartmeut, on which our readers are generally informed.

The partial completion and practical introduction of an elaborate system of elevated street railways, in New York city, is an event of special interest, and, though some serious objections have been found against them, their utility in solving the problem of rapid transit is generally admitted.

The canal across the American isthmus attracted considerable attention at the scientific congresses assembled in Paris during the late exposition, and the results of the several explorations, just made under the direction of the French naval officer, Lieut. Wyse, for a route across the Darien isthmus, enjoyed special prominence. The periodical sending out of expeditions to survey ground that bas been already surveyed and resurveyed in the hope of finding some passage across this troublesome ueck of land, that may, perchance, have escaped the observation of previous expeditions, might as well bs stopped hefore tbe performance becomes farcical. Our own engineers have explored every ridgo, valley, and stream along the whole isthmus from Panama to the Gulf of Sau Blas; and their reports, which are full and exbaustive, fully confirm Trautwine's conclusions, that a canal across tbe isthmus at the narrowest point, from the Gulf of San Miguel to the Gulf of San Blas, with a tunnel of 10 miles in length, at a cost of $300,000,000, is the best that can be donc in a region where nature has interposed so many obstacles. Whether so stupendous a work will ever he undertaken hy private capital and enterprise may well be douhted, and the prediction may, we believe, he safely made tbat the inter-oceanic canal across the American Isthmus, if ever accomplished, will be done by the uuited efforts of the leading commercial nations of the world, in the interest of the world's commerce and of civilization. *Verbum sap.*

The Cape Cod ship canal, a project that has been periodically agitated for a century aud a half, found an able champion, last year, in Mr. Clemeus Herschell; and several schemes for the construction of a direct water-way across the peninsula of Florida were brought forward more or less prominently.

Regardiug the Channel tunnel to connect England aud France, the reclamation of the Zuyder Zee, and the flooding of the Sahara, brilliant projects that havo attracted more or less attention on the part of the engineering world for several years past, nothing has beeu done beyond the regular amount of discussion. The St. Gothard tunnel, the greatest eugineering work at present under way in Europe, met with a serious set-back, last year, hy the refusal of the Swiss cautous to vote the surplus of subsidy which the unforeseen expensiveness of the work has rendered it necessary to provide. The dilficulty, however, appears to have been satisfactorily adjusted.

In mechanics, we have uothing of special importauce to report to the credit of the past year. —*Engineering and Mining Journal.*

Useful Information.

Glass Clothing.

It may seem a transparent falsehood to state that people wear glass clothing, but this sort of apparel may yet come into use. Glass would seem to be about the last thing to think of as clothing; but it is nevertheless true that glass-cloth is being made in Germany. If people who live iu glass houses should not throw stones, it is to be hoped that bad boys clothed in glass may give up their stone-throwing propensities, not to mention snow-balliug, and, if so, the era of glass clothiug will be hailed with pleasure. The following particulars of the process are translated for tbe Detroit *Free Press* from the *Hevrnhut*, by Hermaun Fruecauff, of that city: "At Gaudenfrei, the artist and the glass-spinuer, A. Prengel, of Vienna, has established his glass businoss, offering carpets, cuffs, collars, veils, etc., of glass. He not only spins, hut also weaves glass before the eyes of the people. The otherwise brittle glass he changes into pliable threads, and uses them for making good, warm clothing. It sounds like a myth; hut Mr. Prengel introduces certain ingredients, which are his secret, and therehy changes the entire nature of the glass. He has just finished a white, curly glass muff for a lady in St. Petersburg; he charges 40 thalers ($30) for them. Also ladies' hats of glass, with glass feathers. A remarkable feature of this glass material is that it is lighter than feathers. Wool made of glass cannot he distinguished from the genuine article. Mr. Prengel's glass inventions are something so extraordinary and useful for clothing, etc., as glass is a non-conductor, that it will probably cause an entire revolution in dress material."

Buckwheat.—The name comes from beech-wheat, hecause the seed resembles the beech-mast in shape, but has been corrupted iuto buckwheat. It is a native of Asia, and was brought into Europe either by the Crusaders 600 or 700 years ago, or into Spain by Moors. It did not reach England until within the last 250 years, but just in time to come over with some of the earliest settlers in America. It was first cultivated by the Hudson river Dutch, and by the Swedes on the Delaware. The Dutch meution it as early as 1616, and from what they say on the subject it is quite certain they then knew quite as much about buckwheat cakes as was ever worth knowing. From these two centers of early settlement the cultivation spread over New York, New Jersey and Pennsylvania; following the colonists into the new homes they cleared up in the forests as certainly as the honey bee follows in the pathway of the western pioneer, making his home wherever the white man huilds his cabin. These three States have always been immense producers of buckwheat, growing two-thirds of the whole quantity raised, now amounting to many million bushels annually. Its cultivation is rapidly extending through the north and northwest, until the present annual product is 30,000,000 of bushels.

To Color Zinc.—The *Technologiste* gives the followiug process for permanently coloring zinc. The metal must be quite pure, as must also the materials of which the following hath is composed: Tartrate de cuivre, 30 grains; potasse caustique, 40 grains; eau distillee, 400 grains. After heing submitted for two minutes to the action of this hath, the zinc takes a violet tint; after three minutes immersion, it becomes a deep hlue; in four and a half minutes, green; in six and a half minutes, purple.

Cooling Hot Journals.—You Heeren proposes a method of cooling hot journals hy a mixture of sulphur and oil or grease. The fine metal dust formed when a journal runs hot, and which strongly acts upon both journals and bearing, forms a sulphide of sulphur. This compound, which grows soft and greasy, does not cause any appreciable amount of friction. It has been very successfully used by the steamers of the North German Lloyds.—*Iron Age.*

Warning to Locomotive Engineers.—Drs. Charles M. Cresson and Robert E. Rogers, of this city, says the Philadelphia *Ledger*, well-known as experts in chemistry and dynamics, were appointed by the Reading Railroad Company to inquire iuto aud report upon the causes of the recent explosion of the boiler of the express locomotive "Gem," at Mahanoy City, by which five lives were lost. Their report, which is designed to cover the whols scope of a most careful investigation, is not yet made public, but they have arrived at the following specific conclusion, which we give iu their own language: "We are, therefore, of the opiuion that the explosion of the boiler of the locomotive "Gem," was produced hy the projection of foam upon the heated crowu hars of the furnace, caused by suddeuly aud widely opening the safety-valve at a time wheu tho water had been permitted to get so low as to overheat tho crowu of tho furnace." This is an important matter that should be carefully noted by locomotive aud other engineers.

How to Wash Silks.—Lay the silk smooth on a cleau board, rub soap upou it, and brush it with a rather hard brush. The amount of brushing requisite will depend on the quantity of grease upon the silk. When it has been sufficiently brushed with the soap to cleanse it from grease and dirt, it should be well brushed both sides with clean cold water. A little alum infused in the last water with which the silk is brushed will preveut the colors from spreading. Should there be any patches of grease upon the silk, they should be removed as previously described, for by the applicatiou of a little camphine and alcohol. Folding or wringing silk when wet must be scrupulously avoided, as creases made in silk when wet will never disappear; and, in like mauuer, *hot suds* must not be used for washing silks, as it will in most instances remove the colors.—*Cassell's Household Guide.*

Brier Root Pipes..—Much of the wood used for making the so-called "brier root" pipes is derived, it appears, from Corsica. The white heath, or *bruyere* (of which "hrier" is a corruption), grows in great luxuriance and very abundantly among the trees and shrubs which form what is called the "marquis" covering the mountain sides. In the course of the last few years, since brier wood pipes have become such a large article of trade, the heath trees have become a source of lucrative industry. The roots are dug up and cut into rough forms of tobacco pipes by circular saws worked by the water power of the mountains streams. The pieces, when cut up, are sont in sacks to France, and thence to America, to be eventually manufactured into "hrier root pipes."

The Vitality of Wheat.—The seeds of the wheat possess a vitality which resists intense cold. A sample of the wheat left by the *Polaris*, in 1871, in 81° 16′ north latitudc, aud exposed to a temperature varying from that of summer to that of winter in that position for five years, was sown last year by Dr. Schanburgh, of the Botanic Gardens aud Government plantations, South Australia, and out of 300 grains, 60 germinated and produced plants, three or four feet high, with cars coutaining 30 grains each.

Floating Soap.—A soap that would float upon the water would he often a very convenient thing. Somebody has patented such an article, which is made by simply inserting a piece of cork into the center of the cake. The same result might be obtained by forming the cakes with a small cavity iu the center.

Good Health.

Vegetable Carbon.—The carbou contained in beans, peas, cornmeal, oatmeal, aud other farinacea is of a different character essentially from that which exists in animal fat. The chemist may not find a difference in his last analysis, so far as the elements are concerned, but the dietetic effects are different positively. One may eat largely of vegetable food without the resultant functional derangement which is induced by eating largely of animal fat, notwithstanding that the quantity of carbon may be actually greater by analysis in the vegetablo food. No kind of food will supply the loss of bones. Eat good, nourishing food when suffering from any local disturbauce, like a felon or boil; but avoid oils, fats, grease, and alcoholic stimulants. Eat fruit liherally, so that the blood shall be kept cool and the digestive function in good order.—*Phrenological Journal.*

Health and Happiness.—One of the most important means of securing and retaining good health, is to live happily. Some one has beautifully said: Live in the sunshine at home, although clouds of perplexity environ you in the business marts. Bring smiles into the realm where so much heart service is expended for your comfort. Be a welcome presence to the smallest child, even to the very house dog, to puss upon the rug. A beneficent and loving spirit diffuses its influence from the highest to the lowest. Enter the home as you would some pleasant, safe retreat, where love and pieace await you, leaving behind all that annoys and worries and disturbs you outside. As before marriage you always revealed your better self alone to the eyes of the beloved, so continue to be that higher self throughout.

Gluten and Starch in Wheat.

For the purpose of human food the most valuable coustituents of a grain of wheat are starch and gluten. Starch forms on ths average about 60% of ths kernel; it is ons of the commouest and important articles of food. Gluteu is even more nutritious than starch, its composition being more nearly that of animal substauces, but it is fouud in the wheat kernsl in much less quantity than the starch; in Ohio wheats it may amount to 10% or possibly 15%, while in drier climates the propertion is greater. In additiou to the value of gluten as food, it has properties which make it especially valuable in combination with starch for making bread. It forms, with water, a most tenacious paste, and when fermentatiou or chemical action is set up in dough, this paste forms a thin pellicle about the bubbles of carhonic acid gas as they are produced and retains thom. This retentiou of tho gas causes the dough to expand or rise, so that when haked in this couditiou the hread comes from the oven thoroughly vesicular or light. A flour exclusively of starch or containing insufficient gluten, will not retain the gas, and, consequently, does not rise; the more gluten there is in the flour, the more perfectly the dough made of it rises aud the lighter and hetter the bread. Flour from soft wheats, which contain abundance of starch, but are deficient iu the gluton, command hut a low price for bakers' uso in Eastern cities, while flour from flinty wheat, which is more glutenous aud strong enough to raise itself not only, but possibly a mixture of cheaper flour and a good quantity of water, is in good demand, and at higher prices.—*Health Almanac.*

Sources and Constituents of Cod-liver Oil.—The fish from which the oil now found in commerce is obtained is said by the *British Pharmacopœia* to be *Gadus morrhua*, Lin. In the *U. S. Pharmacopœia* it is said with stricter accuracy to be derived from that fish, "and other species of Gadus." The following are the species of fish from which the oil is ohtained: The codfish, the pollock, the coal-fish, the burhot, the ling and the dorse. The chemical substances which cod-liver oil contains are margaric, stearic, and cetylic acids, all of which are white solids; oleic acid and volatile acids, which are liquids; glycerine and biliary matters, and gaduine. These are shown in tho relative proportions iu which they are contained in the oil, and form a very instructive series. Besides these bodies cod-liver oil contains minute quantities of iodine, bromine, and phosphorus. To each of these its medicinal properties have been referred, hut the minute quantities contained iu the oil, the difference of opinion among authorities, and the fact that other animal oils are found to produce similar effects, seem to prove sufficiently that cod-liver oil is useful chiefly as an easily digested fat.

Pure Air.—Pure air is an essential of pure blood. Pure blood makes stout nerves; consequently pure air which makes the good hlood is an essential of the nervous system. Good nerves insure good digestion; therefore pure air, which through the blood makes the nerves good, is an esseutial of the digestive functions. Good digestiou makes good hlood, which hrings us to our starting point, and proves that pure air is the first element in animal existence. From the cradle to the grave we breatbe every moment, during working aud sleeping hours. Pure living air therefore we require every instant. Bad air is a blood poisouer. Air once passed through the lungs is poisonous. It is not only deprived of its living and life-giving constituents, hut it is loaded with impurities, especially when expired by unhealthy subjects. Fever malaria comes always from poisoned air. There may he no worse poison than the poison emanating from the skins and lungs of a mass of human beiugs If therefore you would escape "hlood-poisoning" have constant free ventilation.

The Morning Cough.—The mucous rheum which calls out the morning cough is due to the changes of temperature to which the lining membrane of the air passages is exposed in cold and stormy weather. People pass rapidly from in-door to out-door temperatures, and tben changes in the vascular supply of tho mucous membrane of the air passages are set up. If everybody at all times only hreathed through the nose, the inspired air would be warmed hy passing over the coils of blood-heated plates which exist in the nose for that purpose, and would not affect the air passages hehind the turhinated bones. But such is not the case; they probably commenco to talk, and in doing so draw in by the mouth cold air, which, on mixing witb the residual air in the chest, lowers its temperature, and then a fluxionary hyperæmia follows, and after it, in its train, a mucous rheum. The best plan for persons who are subject to colds and coughs to adopt, is to keep their mouths closed; talk as little as possible, and avoid stopping or standing still. If one out of doors keeps moving, and with his mouth constantly closed, there is very little danger of taking cold or contracting a catarrh.

Parasitic Skin Diseases.—Editors Press: —The following remedy I would recommend as a safe and reliable cure for skin diseases of the above class, having found it the hest of all the various remedies given in the *Materia Medica*: Two grains of chlorido of zinc to one ounce of distilled water, and use twice a day as a lotion. —Reader.

SAN FRANCISCO:
Saturday Morning, Feb. 8, 1879.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Oil Wells of Ventura County; The Allen Governor; Harrison's Horse Hay Fork, 81. The Week; Openings and Opportunities for Unemployed Labor; Bullion Product of the Principal Mines in 1878; Rapid Transit, 88. Hydraulic Mining Engineering; The Knowles Tank Pump; Big Strike and Early Legends; Notices of Recent Patents, 89.
ILLUSTRATIONS.—Harrison's Improved Hay Fork; The Allen Governor and Valve, 81. Knowles' Tank Pump, with Feeder and Boiler, 89.
MINING STOCK MARKET.—Sales at the San Francisco, California and Pacific Stock Boards, Notices of Assessments, Meetings and Dividends, 84.
MINING SUMMARY from the various counties of California, Nevada, Arizona, Montana, Oregon and Utah, 85-92.
NEWS IN BRIEF on page 92 and other pages.
CORRESPONDENCE.—Chilean Gravels and Gold Washings; Heat of Thermal Springs, 82.
MECHANICAL PROGRESS.—Solidity in Iron Casting; A New Test for Steel; Transmitting Power by Electricity; Transmission of Heat by Steel Plates; Silicide of Iron; Iron Buggies, 83.
SCIENTIFIC PROGRESS.—Ultra-Gaseous Matter; Wood Pulp for Paper; Mean Distance of Water Molecules; Enormous Submarine Plant, 83.
THE ENGINEER.—A Review of the Past Year, 87.
USEFUL INFORMATION.—Glass Clothing; Buckwheat; To Color Zinc; Cooling Hot Journals; Warning to Locomotive Engineers; How to Wash Silks; Brier Root Pipes; The Vitality of Wheat; Floating Soap, 87.
GOOD HEALTH.—Vegetable Carbon; Health and Happiness; Gluten and Starch in Wheat; Sources and Constituents of Cod-liver Oil; Pure Air; The Morning Cough; Parasitic Skin Diseases, 87.
MISCELLANEOUS.—The Tuolumne Cave; Soluble Gold, Silver and Lead Combinations, 82. Cosmic Meteorology—No. 3, 86. The Cone-bearers, or Evergreen Trees of California.—No. 3, 86-87.

Business Announcements.

F. Moorecroft, Stone Seal Engraver, S. F.
Assessment Notice—Wide Awake Prospecting and M. Co.
Assessment Notice—Summit Mining Co.

The Week.

The past week is without domestic events of importance, except the accomplishment of the compromise between the Sutro Tunnel Co. and the mine owners. This will have a very important bearing on future operations on the Comstock. As the snowfall on the Sierra Nevada has been light and but little impacted, the prospect for an extended water season is not encouraging. In the mountain streams there is water enough running to waste to insure prosperity to both the farmer and the miner, were it thoroughly utilized to that end, as it is to be hoped will soon be the case. The low stage of water in our rivers, while it is a detriment to some interests, proves beneficial to others. Good crops will this year be raised on the reclaimed tule land, where all was lost through the breaking of the levees and their overflow last year. And so, while the hydraulic miners may suffer from an inadequate supply of water, the low condition of the rivers will favor those who by wing-damming or otherwise, carry on operations in their beds. It is, nevertheless, the case that an excessively dry season is prejudicial to most of our leading industries, admonishing us of the importance of our constructing ditches and reservoirs for economizing our surplus water and turning it to practical account. The threatened drouth has already had the effect to arouse public attention to the importance of this fact. Schemes for the construction of irrigating ditches, that had been suffered to remain in abeyance, have lately been revived, while many new ones have been planned in those sections of the State where their aid is most needed.

Mr. A. C. Knox, our traveling agent, has started out on a trip through Solano, Yolo and Colusa counties. We hope all our friends will give him what information he desires, and also assist him in increasing our subscription lists.

Openings and Opportunities for Unemployed Labor.

With the late rains the prospects for a good business year in California have been measurably improved. Although we have not yet received sufficient rain to insure for our farming and mining interests the fullest possible prosperity, we have still had enough to make certain for these all-sustaining industries a tolerable success. This is matter for congratulation; the more especially, as our domestic labor market is just now greatly over-stocked, with the likelihood of early receiving fresh and perhaps large accessions from the Eastern States and Europe. Our army of unemployed toilers is already large, and when augmented by this threatened increase from abroad, will be swollen into unwieldly and may be troublesome proportions. With the prospect of so much surplus labor accumulating on our hands, it becomes the duty of the press to point out, as far as may be, the best fields that seem to present themselves for its ready and profitable absorption. It is said that Horace Greeley when applied to for advice, as to the best place for making homes, or finding work, always counseled the applicant to go West. This was no doubt good advice to give in New York, but would not do for San Francisco, since, if followed, it would carry the emigrant to the Sandwich Islands, and, if he kept on, to the empire of China, both poor places for a white man to go to. The Californian in search of work or a place to settle, may go towards any other point of the compass than this, with a fair chance of finding such offer, opening or opportunity as he is looking for, or, as will do to accept.

Let it be premised, however, at the outset, that the era of big wages, rich strikes, and suddenly acquired fortunes is over in California. The "flush times" have vanished with the pioneer days, and can come no more. They must not be expected. We have reached a stage in our industrial progress, that necessitates the great mass of laborers to accept a low wage, and compels capitalists to be content with moderate returns. It will not do as aforetime to stand out for high prices, nor to depend for success on mere streaks of good luck. As a general rule fortunes, or even a competence, is not now to be secured, except through the instrumentality of hard work, while saving has come in as a new and necessary factor of accumulation. Let all who are in want of work and desirous of getting ahead, bear this in mind, and manfully face the inevitable. We will not here read this class a homily on the necessity of their otherwise moderating previously formed expectations, the importance of their practicing sobriety, economy, industry, etc.

It is, of course, generally understood that for the services of artisans, and most kinds of mechanics, craftsmen and others engaged in special callings, there is on this coast no great demand. The class of laborers most required are farmers, miners, teamsters, carpenters, blacksmiths, etc. In certain localities lumbermen, woodchoppers and charcoal hurners are wanted; the first named being needed in the great redwood forests along the northern coast of California, in the lumber districts about Puget sound, along the Columbia, and in the pineries of Truckee, Washoe, Alpine and elsewhere along the Sierra Nevada. As loggers, Maine men are preferred at these places, Canadians being mostly employed as woodchoppers. These men are all paid pretty good wages for the time they are engaged, which, in the Sierra Nevada forests, extend from June to December, work being also somewhat interrupted during the winter elsewhere. The charcoal burners find employment chiefly in the base metal districts, such as Eureka and Tybo, in the State of Nevada, also in Inyo county, California, and in many parts of Utah and Colorado, where they prepare this fuel for the base ore smelting works. The business is largely in the hands of Italians and other foreigners, as they understand it well, and manage to make it remunerative.

Farm hands, teamsters, carpenters, blacksmiths, etc., find, as a matter of course, more or less employment everywhere. With the California farmer there occur two busy seasons during the year; seed time, extending from November to March, and harvest, extending from May to August. During the intervals between these periods he is apt to dismiss most of his help, who loose this time, being unable to get work elsewhere. Most teamsters own their animals and are self-employers, those on hire receiving generally good wages. To those who wish to engage in farming on their own account, nearly all parts of the country present fair openings, provided they have some means to begin with; and if they have not, it is as easy to start here under such conditions as in any other part of the world. Oregon, considering the cheapness of land and the certainty of the crops, presents as favorable chances for grain-raising as any other part of the coast. For fruit culture, the foothills of California are not excelled, this being a pursuit that should prove inviting to many. Dairying is a profitable business where there exist even tolerable facilities for carrying it on. In the vicinity of large towns or prosperous mining camps, an acre or two of ground devoted to the cultivation of choice grapes and fruits has frequently been made to yield a good income. So, too, a small hog, milk or chicken ranch has, in like manner, often proved a source of wealth to the owner. To a patient sort of man, who will attend carefully to his sheep, there is amongst us hardly a better business than wool-growing. Stock-raising is also a very sure, and in the end, profitable pursuit, Nevada, Arizona, and, in fact, nearly all the outside States and Territories abounding with fine sheep and cattle ranges, either wholly vacant or but little occupied.

Then the mines are far from being depleted. Indeed, there is here room for all. It is, to be sure, a rough and laborious life, but there is yet much about mining that ought to draw an ambitious, self-reliant man strongly towards it. To those who wish to engage in this vocation, one section of country presents few advantages over another. Arizona appears to have the call just now, and to the adventurous and strong, able and willing to endure privations and hardships, it offers, no doubt, a very attractive field, its great mineral wealth being pretty well established. But, for that matter, there would seem to be mineral enough almost everywhere. Glowing accounts come to hand of rich ore finds in Nevada, Utah and Colorado, and, in short, from one end of the coast to the other. An extent of placers is said to exist along Snake river and its tributaries sufficient to give profitable employment to a large number of men. Northern California and southern and eastern Oregon also afford good opportunities for engagiug in placer mining. Some diggings of this kind have lately been found in San Luis Obispo, which, according to the local press, promise to yield wages to several hundred men, and perhaps more. There are, all along the gold belt of California, places that could be made to pay fairly through the aid of a little money and the application of some hard labor. To such as are willing to work and to wait, the chances of achieving a final success at gold or silver mining are about as good now as they ever were. Industry, energy and perseverance seldom fail to bring the miner out all right in the end.

Bullion Product of the Principal Mines in 1878.

The following figures, obtained from the various mining companies having offices in this city, or derived from other reliable sources, show the amount of bullion turned out by most of the prominent companies during the year 1878, the yield of the hydraulic, drift, and quartz or vein mines being so segregated as to denote the yearly product of each. Occasionally the officers of these mining companies have declined to give the product of their respective properties; sometimes because the amount was too small to make a respectable showing—oftener, however, for the opposite reason, these parties being not over-desirous of inviting official attention to their large revenues. These tables do not by any means contain the names of all the companies that make a very considerable bullion production, to say nothing of the many small ones that turn out a large quantity in the aggregate, but are too numerous to be individually mentioned.

Hydraulic and drift mining are not prosecuted on any very large scale outside of California. In Oregon, Idaho, Montana, Colorado and Dakota some hydraulic operations are carried on, but the auriferous deposits there are not so extensive nor generally so rich as in California. The net profits realized from this branch of mining are apt to be larger where the conditions are favorable than from any other class whatever, their average amounting to about 75% of the gross production made. In some cases drift operations have also proved very remunerative, though these are more precarious and as a whole much less extensive.

Rapid Transit.

Another and a quicker method of traveling than that which we now possess is one of the great desiderata of the times for cities and their suburban surroundings. It is a universal necessity, and there is money in it. And practical devices, employing inventions in some instances patentable for the protection of the origiuators are wanted, and doubtful problems are awaiting solution. Civil engineers out of employment cannot do better than to go to work on their own account canvassing the local want, and pointing out the way to make it profitable to somebody. A case of this sort in hand at the present time is the Presidio cable road, directed by Mr. Hallidie. What is needed most, however, is rapid transit along the crowded thoroughfares. The horse cars are lamentably inferior. With cheaper fares and more rapid transit, everybody would ride to gain time, even for short distances. The suburbs are still practically beyond the reach of the busy citizen. It is safe to prophesy that it will not be many years before we shall have city transit in all of the large cities at the rate of 6 to 12 miles an hour, stopping only at suitable stations; and suburban transit at the rate of 60 miles an hour. Property is interested in this to the extent of hundreds of millions of dollars; while the whole population of the city is ready to make wholesale contributions to the practical engineer who solves the problem of rapid transit locally without damage to the city property holder. It involves, not merely mechanical ingenuity, but a local canvassing of the routes, and adaptations to the wants of the city.

Another and an equally practical field for ingenuity and enterprise, is the improvement of elevators, by the perfection of systems, for business blocks. This is something that must certainly come in vogue. And the increased value of the upper story offices in the heart of the city, offers sufficient inducement to the engineer as well as to the capitalist.

Aerial Telegraphy.—Among the new scientific wonders is "Loomis' Aerial Telegraphy"—talking with a telephone along any air level without the use of wires, to a distance of 10 or 12 miles. We will await Prof. Loomis' own report on the subject.

On File.—"About Patents," by G. H. K.; "Siskiyou Matters," by J. S. B.; "Amalgamation Processes," by A. B. P.; "Tanning," by T.; and letter with specimens of ores, from H. H., from Corrine.

Hydraulic Mining Engineering.

Taking a look back over this long, gradual growth of hydraulic mining engineering—with its wrought-iron piping under pressure, its improved nozzles, its blocks, riffles, grizzleys and undercurrents, which are bringing in an income for "Uncle Sam" of about $30,000,000 annually—the records of the old Rock Creek water company of Nevada City, which afterwards assumed the name of the South Yuba canal company, have

Beyond a Doubt,

On the authority of the *Transcript*, which has recently investigated them in company with Mr. James Whartenby, water agent of the company at the time, that on the 7th day of March, 1853, Matteson & Brown were engaged in mining on American hill, near Wet hill, a short distance west by north of town, and that they were the pioneers of hydraulic mining.

Matteson, it seems, was an inventive genius of much ability, and after giving considerable thought to the subject as to how the removing of gravel banks might be facilitated, he hit upon the following plan: He

Placed a Barrel

On top of the bank to regulate the head of water that was conducted to it by wooden boxes. Leading from this into the claim was a small canvas hose at the lower end of which was attached a tin branch pipe shaped like a trumpet and two feet in length. On the day mentioned (March 7th) Matteson and his partner, who had been using but eight inches of water previously, increased their order to double that amount.

Mr. Whartenby and D. A. Rich, both of whom were among the very first settlers at Nevada City, give Mr. Matteson the entire credit. They say that Chabet used a hose merely for the purpose of washing off dirt from the bedrock of his claim at Buckeye hill. For several months before

Matteson Came to the Front,

The question of introducing some plan for washing away the banks was vigorously discussed in the camp. The idea was suggested to send East for a hand fire engine; but as it would require the assistance of several men to work it, and wages were then high, it was decided to be impracticable.

George Warren, at his claim on Selby hill, was the first person who used as large a quantity of water from the Rock Creek company as

Forty Inches.

That was in March, 1853, and it made him the laughing stock of all the section.

Passing over the history of our acquaintanceship, slight as it is, with the distribution of the auriferous gravels in our own and in other countries, we have to call attention to the fact that improvements are still being made; and that there is as much room for improvement in mining methods with the aid of hydraulics as there was when Matteson began. Our readers are aware that the

Diamond Sand

Of Cherokee and the float gold of every gravel mining claim in the country, are still evading riffles to a large extent; and that of the many ingenious devices which have been tried and suggested, some of them possessing real merit, are far from being generally introduced, or even generally known. The diamond sand has a market value considerably greater than that of gold, not for ornamental but for industrial purposes; and it is a regular article of trade which the English diamond miners of Africa by no means despise. Leaving the Snake river placer miners to cope with the

Float Gold Problem

As they find it, in the Columbia river basin, let us examine, with "D" in the *Mountain Messsenger* of January 11th, a button retorted from amalgam obtained not from quicksilver placed in the sluices but from fine sand taken up from the sluices and worked by hand. In regard to this sand we were told by Mr. Crane, of the Golden Star drift mine at Alleghany, Sierra county, that, in his opinion, well-skilled miners are constantly allowing the fine gold to escape. He showed "D" two samples of sand. One was of a decided light gray color, and the other a pronounced black. A close examination of each sample revealed

A Marvelous Number

Of glittering gold particles. The sand itself is apparently a finely disintegrated magnetic iron ore, and is so heavy that it settles wherever the fine gold will settle in the sluices.

"I have," said Mr. Crane, "worked all the sand so obtained by the slow and laborious process of a common miner's pan, a little quicksilver and a grinding stone. I am

"Now Erecting

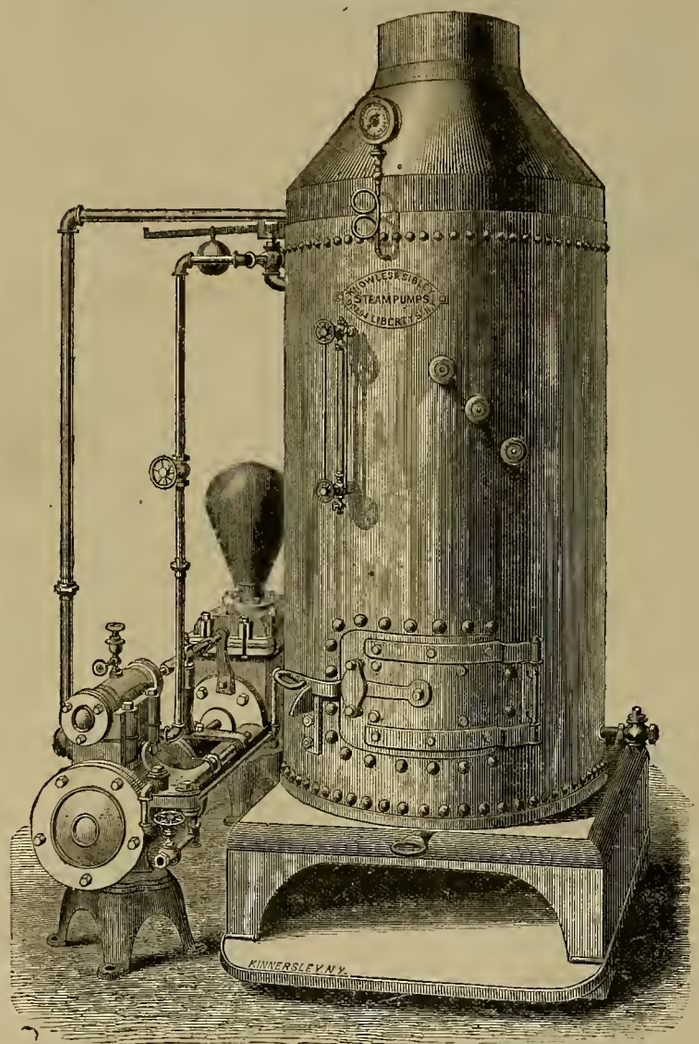
"At our mine, and will have in operation in a few days, an amalgamator of peculiar construction—the joint invention of Mr. C. P. Bowen and myself—which I confidently expect will work this sand at the rate of 50 tons a day, and save the very last atom of gold. If the miners would give their sluices close scrutiny and careful tests, the fact would be discovered that an astonishing percentage of gold is lost in defective sluices and through the carelessness of those who gather the harvest after all the work has been done."

The Knowles Tank Pump.

The engraving on this page represents a 7½-inch Knowles patent tank steam pump, with feed pump attached and boiler ready for work. This machine is used for forcing water from springs or rivers to hotels, public or private institutions, residences, railway stations, brickyards, breweries, etc. In this form it is portable and complete, and can be placed at the point from which water is to be taken, and the water forced by it to the distance and hight required.

It does not require the attention of a skilled mechanic to operate it, as it is furnished with all appliances the most complete, including steam and water gauges, gauge cocks, safety-valve, etc. Its entire management can be learned in a few hours.

The boiler is fed directly from the main pump, or a small plunger pump is attached to the piston-rod of the main pump for that purpose. The boiler and attachments are of the best manufacture. The regular (numbered) sized pumps in the price list of the agents, are calculated for feeding steam boilers and forcing



KNOWLES' TANK PUMP, WITH FEEDER AND BOILER.

water under pressure or to a high elevation.

The tank pumps are made especially for raising water or other liquids into tanks or reservoirs for railroad stations, tanneries, oil works, mine works, etc. Where a great hight is not required, the tank pumps should be used, as giving a larger quantity of liquid with a lighter and less costly machine. The tank pumps have a plunger pump attached, for feeding the boiler. These can be attached to regular sizes, making a separate feed if desired. This is a compact, effective, durable, and at the same time, simple machine; and forms one of the most complete arrangements of the kind offered to the public. The sole agents for this coast are A. L. Fish & Co., Nos. 9 and 11 First street, near Market, San Francisco, who are also dealers in all kinds of new and second hand machinery.

The Kendall One Stamp.—One of the Kendall one stamp mills, which we recently illustrated in the PRESS, is running at Rough and Ready, near Grass Valley, and is said to be crushing *six* tons per day, giving excellent satisfaction. Another is running at Sonora, Tuolumne county, and there are three in Amador county. One has also gone to Carihou. When this item appeared last week, a typographical error made us say the mill was crushing *one* ton, when it should have been *six* tons per day.

Big Strike and Early Legends.

The Tuolumne *Independent* gives the following account of a recent gold find, with which are coupled some reminisences of early days in that county: Thomas Adams, who before for a long time had been in poor luck, struck a pocket the other day at Union hill from which he took $254 in two pans of decomposed quartz, with a good prospect for finding more. He had been running a tunnel into his claim, but not finding anything, he went on the surface and began digging again in a shallow hole, made there a year since. At almost the first lick with his pick he struck into this rich deposit, which was scarcely six inches from the point where he knocked off last year. This quartz vein is supposed to be a feeder of the Peck placer claim, one of the richest ever struck in the county. Capt. Peck, after whom it was named, came here in 1851, and for awhile found it difficult to make enough to keep him from starving. At this time Joaquin, the brigand, had just opened this claim, which was paying him largely. Taking pity on Peck because of his poverty he gave him a pan of dirt, which, on being washed out, yielded $25. The ingrate, knowing that a Mexican was not allowed under the local laws to hold any mining ground, associated himself with two other equally detestable characters and proceeded to drive his benefactor from his claim, which, after they had taken possession of it, yielded them many thousand dollars. After these three men had abandoned the ground, supposing it to be worked out, others came in, and opening it up further, also took from it a good deal of money. It is said that Joaquin was in like manner driven from other claims, which, with au outrage committed on his wife, so imbittered him against the whites that he became their lasting and deadly enemy. This man Peck afterwards located and worked another rich claim under Table mountain, and which, when nearly exhausted, he managed, through false representations, to sell for a pretty good sum. When some years later he was killed in the lower country by a runaway horse, his death excited little commiseration in the community where he had resided and where his sharp practices were so well known.

Sutro and the Comstockers have come to terms.

Lead is again in active demand in New York,

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s Scientific Press American and Foreign Patent Agency, the following are worthy of special mention:

Rotary Vacuum Engine.—Dr. L. B. Lawrence, Monticello, Yolo Co. Dated January 28th. This is a novel apparatus, which the inventor calls a rotary vacuum engine, and it consists of a circular arrangement of open tubes which are provided with valves at one end. These tubes are so constructed as to become charged with hot air or vapor during the revolution of the apparatus, which is mounted on a horizontal shaft. The lower end of the rim formed of these tubes, dips into a tank of mercury, water or any suitable liquid, and the continuous revolution of this rim brings the section of the tubular circumference successively below the liquid. The valves at the opposite ends of the section will be automatically closed, and the atmospheric pressure upon the closed ends of the tubes will force them continuously beneath the surface of the liquid. The heated air may be supplied from a suitable heater, so arranged to fill each section of the tube successively just previous to its immersion in the liquid, or it may be provided by a gas jet, which is alternately ignited and shut off; or, if desired, the tubes may be filled with steam or other vapor to be condensed. Suitable mechanism is connected with the axle, by which the various valves are opened or closed, or the tubes supplied with heated air or vapor.

Combined Sulky and Walking Rake.—A. Ahbey and G. Brammar, Livermore, Alameda county. Dated, January 28th, 1879—This invention relates to an improved wooden tooth combined sulky and single walking revolving rake; and the improvements consist in so attaching an ordinary single walking revolving rake to a sulky that its operation may be controlled by the driver from his seat without any one being compelled to walk behind to attend the handles regulating the detaining block which controls the teeth of the rake. It also consists in forming the connections between the sulky and walking rake so that they may be separated, and the walking rake used in the ordinary manner for rough and hilly land. The connections are simple in construction and operation and the whole device strong and practical. It admits of the use of wooden revolving teeth, while at the same time a sulky can be used and the driver may ride. The usual form of teeth in use for sulky rakes are curved metallic ones, which collect considerable dirt in the grain or hay. The revolving hand rakes with wooden teeth are usually preferred, but with their use the driver has to walk. In this device the useful features of both rakes are combined, while the combination may be broken if desired, and the walking rake used as such on hilly or rough land.

Diaphragms for Furnaces.—M. D. Haskins, Guernsville, Sonoma county. Dated, January 28th. This invention relates to an improvement in that class of furnaces in which ore is roasted by dropping in from one to another of a series of diphragms which are placed horizontally in a vertical furnace, and the improvement consists more especially in a novel method of constructing these diaphragms so that they will resist the effects of the heat, and not give way under the load. When the diaphragms are made of tile or other plates as is usual in this class of furnaces, they will not stand the combined effects of the heat and the weight of the ore, and they soon sink in the center, and eventually fall through, and render the furnaces useless. In order to remedy this, and produce diaphragms which will stand the pressure, the inventor forms them of cast iron in sections so as to be readily introduced or removed, and these sections are united and provided with a system of radiating ribs projecting below the diaphragms and sustaining its center so that when heated they will resist the tendency to sink and bend under the load.

Machine for Cleaning Fiber.—Thos. McAuley, S. F. Dated January 28th, 1879. This is a machine which is intended to dry and cleanse, or, in some cases, to cleanse alone, all sorts of vegetable fiber, hair, and similar substances. It is more especially intended for cleaning the fiber of the cocoanut bark, and consists of a revolving drum, the outside of which is composed of slats slightly separated from each other, so that dust may fall out. A number of blocks are placed within the drum with the fiber, and through the center a hot drum may pass for the purpose of drying the material when necessary.

Transmitting Power.—Wm. Meyers, Oakland. Dated January 28th, 1879. This invention relates to an improved machine for transmitting power, and the improvements consist in the combination with a driving water wheel, crank, or pulley and its shaft, of certain combination of mechanism, whereby the inventor is enabled to transmit the power either increased or diminished from that of the source, and to distribute it, so that it may be easily employed at four or more different points at once, or it may all be concentrated if desired.

DEWEY & CO.

American & Foreign Patent Agents

OFFICE, 202 SANSOME ST., N.E. COR. PINE, S. F.

PATENTS obtained promptly; Caveats filed expeditiously; Patent Reissues taken out Assignments made and recorded in legal form; Copies of Pateuts and Assigaments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; Every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to ahundantly satisfy our patrous; and our success and business are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable iuventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitatiug their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure, with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Baden, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuha, Roman States, Wurtemburg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Granada, Chile, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign pateut laws—agents who are reliable and permauently established.

Our schedule price for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We *can and do* get foreign patents for inventors iu the Pacific States from two to six months (according to the location of the country) SOONER than any other agents.

The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more correctly judge of the value and patentability of inventions discovered here than any other agents.

Situated so remote from the seat of government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars free.

Home Counsel.

Our long experience in obtaining patents for Inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless applicatiou by pointing to them the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applicants which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of pateuts or purchasers of pateuted articles, can often receive advice of importance to them from a short call at our office.

Remittances of money, made by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants bave not only lost their money, but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency.

Engravings.

We have superior artists in our own office, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

Patents for Mining and Farming Lands.

Having complete arrangements with competent and reliable parties in Washington City, by which we are able to secure prompt and careful attention to law business there, we are prepared to assist Mill and Mine, Canal and Ditch owners in securing patents for their lands, mines and claims, in addition to our general line of pateut business.

Many who are acquainted with the manner in which this business has heretofore been conducted, (with or without assistance by local attorneys), will see at once the great advantage of patronizing an establishment that is thoroughly organized and has its represeutatives in Washington to look after and prosecute their applications before the Commissioner of the General Land Office. The business on this Coast will be attended to personally by a member of our firm, and satisfaction will be given in all respects.

Correspondence from persons desirous of securing patents for Lands, Mines, Mill Sites, Canal and Ditch property, promptly attended to.

Applicants for patents for mining and farming land, whose claims have been delayed for any reason, will find it to their advantage to consult with us and in case of necessity secure the services of our home and Washington branch agency.

DEWEY & CO.,

Solicitors of Patents for Lands, Mines and Inventions, MINING AND SCIENTIFIC PRESS OFFICE, No 202 Sansome St., San Francisco

REGISTER YOUR TRADE

MARKS.

The U. S. Government now offers greater protection than formerly to manufacturers under the law of Trade Marks.

Those who manufacture a superior article, or put up improved packages of merchandise, should protect themselves from imitations by registering their Trade Marks.

We have special facilities for securing full rights by the registration of Trade Marks, and our terms are very reasonable.

Consultations free. Many dealers have missed fortunes from not being fully informed and protecting themselves in their rights.

BUYER —AND— COMMISSION MERCHANT.

The undersigned, after an experience of forty years in the Grocery Business, has opened an office at No 24 CALIFORNIA STREET, corner Drumm, for buying and selling all kinds of Goods. Parties throughout the States and Territories wishing an Agent in this Market for the transaction of their business, by entrusting the same to me, I can have special rates made, with full guarantee of satisfaction, or no charge for services.

With twenty-five years' experience in this Market, I think I can suit one and all, both as a buyer and seller. All I ask is a trial. I will also have a Ladies' Department, under the management of a lady of experience and taste, who will fill all orders for your wives and daughters. Orders for this this Department should he endorsed: "For Lady Buyer."

All parties ordering will be required to send funds with order or satisfactory reference. Respectfully,

WHEELER MARTIN,

CAUTION
To Hydraulic Miners.

The public generally and Hydraulic Miners especially are hereby notified that any parties making or using the contrivance known as the HOSKIN DEFLECTOR will be prosecuted to the full extent of the law, said machine having been declared by the U. S. Circuit Court an infringement upon my patent, the

Bloomfield Deflecting Nozzle.

The public are also cautioned against using the Hoskin Deflector because of its danger to life and limb, this device having already occasioned several deaths and other serious accidents. The BLOOMFIELD DEFLECTOR is entirely safe, its two and a half years use without accident, as well as its construction, proves it to be a reliable contrivance.

Any parties wishing to purchase the right to use these Deflectors can do so by applying to the undersigned,

HENRY C. PERKINS,
North Bloomfield, Nevada Co., Cal., October 1st, 1878.

Pocket Map of California and Nevada.

Compiled from the latest authentic sources, by Chas. Drayton Gibbs, C. E. This map comprises information obtained from the U. S. Coast and Land, Whitney's State Geological, and Railroad Surveys; and from the results of explorations made by R. S. Williamson, U. S. A., Henry Degroot, C. D. Gibbs and others. The scale is 18 miles to 1 inch. It gives the Judicial and U. S. Land Districts. It distinguishes the Townships and their subdivisions; the County Seats; The Military Posts; the Railroads built and proposed, and the limits of some of them; the occurrence of gold, silver, copper, quicksilver, tin, coal and oil. It has a section showing the hights of the principal mountains. The boundaries are clear and unmistakable, and the print good. 1878. Sold by DEWEY & CO. Price, postpaid, $2; to subscribers of this journal, until further notice, $1.

[Continued from Page 85.]

regard to the mines. They are looking well and over 70 tons per day of ore is being taken out.

ESMERALDA DISTRICT.

THE DEL MONTE SHAFT.—*Herald*, Feb. 1: Last week a vein of water was cut in the bottom of the Del Monte shaft which necessitated an increased number of strokes hy the pump, and now quite a large stream is flowing down the canyon from the company's works. This affords the town a good supply of water.

SHAW DISTRICT.—*Silver State*, Feb. 1: This mining district, discovered last fall, is situated 27 miles north of Winnemucca on the east or Paradise side of the range of mountains which divides Quin's river and Paradise valleys. The Eclipse mine, the first located in the district, runs as far as developed northeast aud southwest, and is about 20 feet wide. The side of the mountain below the croppings is covered with float rock, which assays from $30 to $550 per ton in gold aud silver. The Eclipse has been bonded by W. H. Howard, who has four men employed on the mine sinking a shaft. There seems to he no question as to the richness and extent of the ore, and it is confidently expected that a prosperous mining camp will spring up here next spring. The proximity of the district to the railroad and the advantages which it has in fuel and water, make the locality one of the most inviting in the country.

EUREKA DISTRICT.

MINING ITEMS.—*Sentinel*, Feb. 2: Albion stopped work for the present. About 150 men are employed at the Richmond. Nearly 200 men are carried on the pay roll of the Eureka Consolidated. From the Graut mine, on McCoy Hill, they are taking out some first-class ore. The Charter Tunnel company have au 8-inch streak of rich ore in the Needle mine, and are working at it diligently. Work at the Richmond seems to progress as usual, without hitch or break of any kind. A large amount of ore is being hoisted and sent to the smelter every day, to increase the bullion product of 1879. Black metal ore, of a high grade, has been struck iu the Prospect Mountain tunnel, at a distance of 900 feet from its mouth, and which is 600 feet below the surface of the mountain. The company have prosecuted work on this enterprise for about two years, and this is tbe first substantial indication of a return that they have met with.

REESE RIVER DISTRICT.

MANHATTAN.—*Reville*, Feb. 1: During the past week the mill has reduced 130 tons of ore of the assay value of $28,047.55. Of this amount $10,278.12 was from custom ores, $3,488.80 from tribute mines and the balance, $14,280.63, from the Frost and Curtis shafts.

WESTERN NYE.—It is rumored that negotiations bave about been completed in San Francisco for the sale of the Illiuois miue and furnace to Eastern capitalists. The Alexander mill ehut down on the 27th ult. for a few days in order to repair the conveyer and make a general cleanup. The company have since shipped five bars of bulliou.

WHITE PINE DISTRICT.

CHLORIDERS.—It is reported that the chloriders who have been working in the upper levels of the old Eberhardt & Aurora mine, in White Pine, have made the discovery of another extensive ore body. We hope the information may prove true, as it would give a large numher of persons employment. It is only a matter of time when good mines will be struck in tbe county.

ARIZONA.

MINING NEWS, ETC.—*Silver Belt*, Jan. 31: The McMillen company has men at work grading for the new mill. Four men are now at work on the Maimi mine, and good ore is still being extracted. The Gold Hill district is attracting attention, miners obtaining good results. Salter & Lieurance have commenced work on their claim, adjoining the McCormick. Some fair looking ore has been exposed. The Silver Queen shaft is down 109 feet. Crosscutting will not be attempted until a depth of 150 feet is reached. Neil Dongherty is taking 400 ounce ore out of the west half of the Richmond. The pay streak two feet wide gives that results. Balance of the vein, tbree feet, is said to be fair milling ore. The sbaft on the Alice mine is down 80 feet. For the last 18 feet there has been fair ore found, and tbis has recently improved so much that it is believed to be worth $200 per ton. The intention is to go down 100 feet, and then crosscut, when the probability is that a good body of ore will be exposed. The Brilliant lode, about six miles northwest of McMillen, promises to become a good mine. It bas been opened to the depth of 70 feet in good ehape, the shaft heing securely and neatly timhered. The vein exposed in a drift is about four feet wide, witb smooth, solid wall, and of this there is about 15 inches on the banging wall which shows hunches and streaks of ore that will assay $10,000 per ton, but taking the whole of this part of the veiu it is estimated that by assortment it will yield about $300. A company has purchased a small mill, with a view of erecting it at Tonto Basin.

THE ISABELLA CO.—G. S. Holbrook, one of tbe Directors of this Co., in a letter to the *Mining Record* says four or five of the mines "bave been so well opened and tested, that there can be no longer the least douht as to their great and permanent value." The mines have not been developed at all, as our readers very well know. The veracious Holbrook ends his effusion by stating that he confidently expected dividends in January, but might "possibly he obliged to wait until some time in February." As the Haskin mill is standing idle, no work is being done on the mines, and one of the best of the eight claims has been "jumped," that is, relocated by one of Mr. Bixhy's former hosom friends and lieutenants, the prospect of dividends being paid is rather remote.

MONTANA.

PHILLIPSBURG.—*New North West*, Jan 31: The Frue Vanners of the Hope, after a detention of three weeks to perfect certain necessary repairs to building, started up again on the 14th inst., and are now busily engaged in working concentrations from this company's immense tailing deposit. Driving the incline at the mine to tap the ore body at a greater depth is being done with dispatch. The Northwestern company, as usual, is ruuning steadily, working ores from Trout and Poorman. The water column and steam piping for this company's new pump has been placed in position in the Trout shaft by Engineer Gump. Everything now in readiness for deeper working. The Algonquin is being slowly and steadily drained, the powerful piston pump, now in position, working finely. Murray & Durfee are driving the tunnel ahead to crosscut the Blackmail. The Laiblin contract on this tunnel has been completed in an excellent and creditable manner. At Butte, the Lexington foundry is ready to fire up on its first charge wheuever the proprietor chooses to give the word "go." The quartz mines at Red Bluff are looking first-rate, and the miners there will make plenty of money when they can get their ore crushed.

OREGON.

GOOD OUTLOOK.—*Times*, Jan. 27: We are informed by parties from Josephine county that there is every prospect of Silver Creek proving a rich camp—one that will afford remunerative mining for several years to come. Favorable accounts from there are reported.

UTAH.

JACKSON.—Salt Lake *Tribune*, Feb. 2: According to the latest news from this district no ledge has been struck in the new camp, but large quantities of float have been found, and some 200 locations covering tbe whole mountain made in the hope of striking blind ledges. Of several assays made at the Reef of float ore tbe aggregate showed $1,100 in silver and $300 in gold. It seems to be pretty well settled that good ore has been found on the surface, but the ledges are deeply covered with debris and remain to be discovered by uncovering.

BULLION AND SMELTERS.—McCornick & Co. yesterday received another carload of bullion from the Watterman emelter, Stockton. Campbell, Cullen & Co. have about half completed a contract to ship 50 carloads of their bullion to a Pennsylvauia lead works. The Morgan smelter yesterday received from White & Shiloh, Battle Mountain, Nevada, two lots of sulphides, one lot assayiug $96.03 to the tou, and tbe other over $1,100. Water was turned iuto the canal of the Old Telegraph works a few days since, but it again broke over the bank and caused a further delay. The break, however, was small and was soon repaired, so that the smelter will be started up to-day, and the production of bullion recommenced. The Chicago smelter, at Rush Lake, Tooele county, which has been so long idle, will be started up to-day by Messrs. Brooks & Davis, and a successful run is expected

FOR THE YEAR.—*Silver Reef*, Jau. 25: The Ontario mill and mine, notwithstanding the burn-out in November, stopping operations for several weeks, produced during the year of '78 $1,462,373,56. On the 16th inst. its shareholders received tbeir 39th dividend—50 cents on the share and making $1,950,000 paid in dividends to that date.

MINING NOTES.—We are reliably informed that tbe ore in the Last Chance mine shows in some places a thickness of 25 feet. The shipment of bullion from Silver Reef, through Wells, Fargo & Co., for the week ending January 25th, 1879, aggregates $23,028. The Luna mine sbows a vein of ore more than six feet thick, and the foot wall not yet reached. A strike was made on the 24th inst., in the Stormont mine, which hids fair to astonish the nativcs. The compauy was employed in running down their incline in order to get at and control the water, and were keeping it on a regular grade to accommodate the car. In cutting away what they supposed to be tbe hanging wall to make place for tbe pump, the ore was broken down. Two loads of it takeu to the mill worked $471.70 per ton. The extent of tbe strike bas not yet been determined, but tbe indications are that it is extensive. Ye disgusted miner, in squads of from two to fifty, are expected in this afternoon from the played-out Paria diggings. It is not supposed that there will be any cussing. Oh, no.

PRACTICAL CHEMISTRY IN GOLD AND SILVER EXTRACTION.—Mr. C. H. Aaron in this issue discusses several mooted points in connection with lixiviation processes, which are referred to the "Chemical Section," and to those who have tbe use of the laboratories at Berkeley. For a resume of the natural and artificial solutions and precipitations of gold and silver so far as known at the time, reference may be made to a tabular statement in Bowman's study of the "Vein Geology" of the Sierra, published in Raymond's report for 1875.

News in Brief.

REV THOMAS K. BEECHER favors cremation.

FAMINE in upper Egypt is reported as dreadful.

GOVERNOR HARTRANFT signed fifty deatb warrants.

POTATOES sell in Washington Territory at 50 cents per bushel.

THE police of this city made 1,568 arrests during January.

STANLEY is announced in London for another African exploratiou.

QUAILS are very abundant in the foothills of San Luis Obispo county.

THE discount rate of tbe Bank of England has been reduced to 3%.

AN agitation on Chinese immigration is prevailing in New South Wales.

THE wild geese have commenced their northern migration; many could be seen the past week passing over this city.

HORSES are dying about Walla Walla, Oregon, with the glanders.

A NUGGET of gold worth about $104 was lately found on Silver creek, Oregon.

IN a street fight at Austin, Tex., the sheriff was killed and two other persons wounded.

THE *Transcript* says the prospects of Nevada county were never hetter than at present.

SEVERAL thousand engineers, boiler-makers, fitters and dock laborers struck at Liverpool.

HEAVY frosts in the northern coast counties have so kept back the grass that feed is poor.

MOST of the southern cities are slowly recovering from the disasters brought upon them by the war.

THE plague has made its appearance at Moscow and is causing great alarm in many parts of Europe.

THERE are 103 boys, between the ages of 14 to 19, confined in the State prison at San Quentin.

WITHIN the past three monthe 3,000 people have joined the Blue Ribbon Temperance Club in Oregon.

A STRONG feeling exists among leading colored citizens of Louisiana favoring migration to other parts of the Union.

A BILL before the Nevada Legislature proposes to exempt printing material to the value of $2,500 from execution.

SNOW on the mountains is driving the wild pigeons in large numbers down iuto the valleye of Yolo and Solano counties.

A SUFFICIENT quantity of snow has already fallen this season to admit of running the mills along the Carson river during most of next summer.

BUSINESS of all kinds is said to be improving in the Atlantic States. Work is getting more plentiful, though wages, like everything else, are low.

IN Los Angeles laundries are taxed $25 per month each; vegetable pedlars $50, and every Chinaman employed in the city in any capacity must pay $6 per month.

WHILE the salmon cannerymen on the Columbia river complain that last year's business was profitless, tbey are proposing to engage in it extensively the present year.

THE edge of Clear lake, for many yards from tbe shore, has several times been frozen this winter. Even the aborigines have been astouished at the occurrence.

SENATOR CHRISTIANCY bas notified tbe President that be will accept the Peru mission—salary $10,000—and resign as United States Senator from Micbigan.

RESULTS of recent inquiry into the origin of epidemic diphtheria in New York indicate the probability that it is frequently caused by using milk of cows affected with garget.

IT is said that a quantity of tellurium bas been found in tbe Central Hill mine, Eureka, Nev. This article is used chiefly in edging cutlery, and commands a fabulous price.

RECENT rains have furnisbed an abundance of water for mining purposes, and all claims in Calaveras, for tbe first time tbis season, are now being worked to tbeir fullest capacity.

A LARGE deposit of kaoline, a clay used in the manufacture of terra-cotta or fancy pottery, has been struck in tunnel No. 4, South Pacific Coast railroad, Santa Cruz county.

EDWARD NILES, General Ticket Agent for the Virginia and Truckee Railroad Company, was recently taken to the Pacific Insane Asylum at Stockton; cause of his insanity, losses in stocks.

REGISTRAR KAPLAN denies that tbere bas been an increase of 5,000 voters since the last election, and says that the total new registration in this city since the 19tb day of June last is only 366.

MRS. CLARA S. FOLTZ has been admitted to practice as an attorney by tbe Fourtb District Court and has opened a law office in tbis city, she being the first woman ever admitted to the bar in this State.

ABOUT 200 persons bave left Silver Reef, Utah, for the new El Dorado. Letters from the Buckskin mountains say that the crowd has gathered at a point about 35 miles nearly south of Johnson, but that no important discoveries are made yet.

SARGENT'S bill to provide a new Postoffice for San Francisco leaves the selection of tbe site to the Secretary of the Treasury, and appropriates $500,000 for the purchase of a site and the commencement of the building, the total cost not to exceed $3,000,000. Tbe Palace Hotel could be bought for that, and no better site or building could be had for the purpose.

Personal.

ARIZONA.—Ex-Mayor F. W. Blake, who has for a long time had the mauagement of the finances of tbe Peck Miuing Co., has been appointed agent and general Superinteudent of the affairs of the company in Arizona, with his office in Prescott.—*Miner, Prescott, Jan. 24th.*

MONTANA.—Robert E. Strahorn, editor of the *New West*, and autbor of "To the Rockies and Beyond," made Butte a one day visit last week. Mr. Strahorn has traveled extensively over Montana, and more, perhaps, than any other of its citizens has he assisted in making the outside world acquainted with its great resources.—*Butte Miner, Jan. 14th.*

COLORADO.—Prof. N. P. Hill, the genial Superintendent of the Central City Smelting Works, has been elected U. S. Senator, with evident satisfaction to the mining interest.

WHAT MIGHT HAVE BEEN.—In a report just forwarded to the Secretary of the Interior, Gen. Fremont says: It is interesting to speculate on what might have been, bad this southern line been already built before the war. True to the instincts of commerce the northern road has swept round through Califoruia and is entering Arizona from the west, while other great roads are converging into it from the east and north. Arizona is the natural gateway of commerce and travel between the States east of the Mississippi, and California and the Pacific Ocean. Fronting on Mexico it is in position to profit by any developments which may result from tbe awakened interests of our merchants and manufacturers in the trade of that country. You will remember that before our civil war, Congress bad directed examiuations for an overland route to the Pacific, to be made on four different lines between the 32d and 46th parallels, and upon comparison of results by the War Department, tbe *32d parallel was declared the best.* A bill was accordingly framed adopting this liue; and with a large grant of lands and money had already passed the House and wae about passing the other, when events occurring in Texas were announced in Congress, and the liue of the road thrown to the north. Passing together through this gateway of Arizona the united road will enter Mexico by a trunk line, which will be nourished by ten millions of people and the sea of Guaymas, while the braneles penetrate the States.

RESPONSIBILITY OF ARCHITECTS.—The question of holding architects personally responsible for the safety of buildings erected under their supervision, is placed prominently before the public by the action of the Institute of Arcbitects, which recently held its regular annual convention in this city. The Rhode Island Chapter of that body has framed a law which is intended to change the existing conditions by making faulty work a penal offence, punishable by fine and imprisonment. It is proposed to apply this rule to contractors, builders, and architects alike. In France, architects and builders are held responsible for a building for 10 years after its completiou. There is no reason why such a law should not be enacted here.

THE New York Immigration Commissionere report a large increase of European prepaid passage tickets over last year, and anticipate for the current year 20% more, or 120,000 emigrants. Of operatives alone, 20,000 are expected withiu tbe next few months.

THE Los Angeles woolen mills are in full operation, aud have already made several tbousand dollars' worth of blankets and flannels.

HEAVY business failures continue in England.

Our Eastern Agency.

We have established a special Eastern Agency for the PRESS at No. 38 University Place, New York City, with MR. JOHN MICHELS. He will correspond for our columns, and also receive subscriptions, advertisements, etc., for the accommodation of our Eastern friends.

FRESH attractions are constantly added to Woodward's Gardens, among which is Prof. Gruber's great educator, the Zoographicon. Each department increases daily, and the Pavilion performances are more popular than ever. All new novelties find a place at this wonderful resort. Prices remain as usual.

ARTESIAN WELLS WANTED.—Parties who are prepared to contract for boring artesian wells are invited to send terms to Edward Frisbie, proprietor of the Reading Ranch, Anderson, Shasta County, Cal.

SETTLERS and others wishing good farming lands for sure crops, are referred to Mr. Edward Frisbie, of Anderson, Shasta County, Cal., who has some 15,000 acres for sale in the Upper Sacramento valley. His advertisement appears from time to time in this paper.

EXAMINE the accelerative endowment plan, as originated by the Mutual Benefit Life Insurance Co., of Newark, New Jersey. Assets, $30,533,429.94. Lewis C. Grover, President; L. Spencer Coble, Vice-President; Benjamin C. Miller, Treasurer; Edward A. Strong, Secretary; Bloomfield J. Miller, Actuary. Send for circulars to James Munsell, Jr., agent of insured, 224 Sansome St., San Francisco.

EXPERIMENTAL MACHINERY, drawings, patterns, models, all kinds of electrical and telegraphic apparatus to order. See ad. F. W. FULLER, 415 Market St., second floor, S. F.

HENRY R. EWALD is our general correspondent and agent for Arizona.

Total rain during the season, from July 1, 1878, 9.650 in.

We have on hand some 400 to 500 lbs. of brevier, in good condition, for sale at a bargain. Will sell a part only if desired. Second-hand cases to match. Also a font of bourgeois in first-rate order, with cases. Also a cabinet and upwards of twenty fonts of good display type, not very old and but little used. Some of the fonts are large,

Printing Type For Sale Very Low.

of modern style, and what might be termed good substantial display type for advertisements and job printing.

A good proof press will also be sold at a greatly reduced price from cost.

We can fit out a good country printing office nearly complete at a moderate cost. Call and see the material.

DEWEY & CO.,
Publishers, No. 202 Sansome street, San Francisco.

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued, wholesale and retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS Office, S. F.

BY GUIDO KUSTEL,
MINING ENGINEER AND METALLURGIST.

Roasting of Gold and Silver Ores, and the Extraction of their respective Metals without Quicksilver. 1879.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore

It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus.

It is a work of great merit, by an author whose reputation is unsurpassed in his specialty.

Price, $2.50 coin, postage free.

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867.

This work is unequaled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Millman, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery, etc., which alone are of the greatest value. PRICE, $7.5

ARITHMETIC MADE EASY
BY ROPP'S
Easy Calculator.

This valuable work is used by thousands of farmers, mechanics and business men, and is highly recommended for its practical utility and convenience.

It embodies an entirely new system of calculation, by which a vast amount of figures and mental labor—required by the ordinary methods—and fractions with their complexities, are absolutely avoided.

It is so simple and easily comprehended that even the most illiterate is enabled, in a few minutes, to reckon with absolute accuracy and speed; while its original and rapid methods, benefit and delight the most scholarly.

It shows at a glance the accurate value of wheat, corn, rye, oats, barley, cattle, hogs, hay, coal, lumber and merchandise, from one pound to a car load, and for any price the market is likely to reach.

It gives the interest, simple and compound, on any sum, or any time, at six, seven, eight, and ten per cent.; the exact measurement of boards, scantlings, timbers, saw logs, cisterns, tanks, wells, granaries, bins, wagon beds, corn cribs, etc., the wages at various rates, for hours, days, weeks and months; besides numerous other important methods, rules and tables.

It is printed on fine tinted paper, is well and elegantly found in pocket-book shape, and accompanied by a silicate slate, pocket for papers, and memorandum, which can be replenished in the two latter styles.

It answers the purpose of a pocket book and diary, and costs no more, although it was gotten up at great expense and labor, and is unquestionably one of the most useful publications ever issued from the press.

Price, bound in Fine English Cloth, $1.00.

Sent direct from the Eastern publisher, postpaid, on receipt of price, by P. O. order, registered letter or receipted by express. Address

DEWEY & CO., San Francisco.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

Cherokee Flat Blue Gravel Company.—Location of principal place of business, San Francisco. Location of works, Cherokee Flat, Butte County, California.

NOTICE.—There is delinquent upon the following described stock, on account of assessment (No. 40), levied on the 20th day of December, 1878, the several amounts set opposite the names of the respective shareholders, as follows:

	No. Certificate.	No. Shares.	Amt.
A. Casselli	17	4608	$230 40
L. Nusbaum	105	50	2 50
E. L. Pfeiffer	106	430	21 50

And in accordance with law, and an order of the Board of Directors, made on the 20th day of December, 1878, so many shares of each parcel of such stock as may be necessary, will be sold at public auction, at the office of the company, on Tuesday, the 18th day of February, 1879, at the hour of two o'clock, P. M., of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of the sale.

R. N. VAN BRUNT, Secretary.
Office, No. 318 Pine Street, Room 6.

Griffith Consolidated Mill and Mining Company.—Location of principal place of business, San Francisco, California. Location of works, Diamond Springs Mining District, El Dorado County, California.

Notice is hereby given, that at a meeting of the Board of Trustees, held on the 21st day of January, 1879 an assessment (No. 1) of twenty cents (20c) per share was levied upon the Capital stock of the Corporation, payable immediately to the Secretary, at the Office of the Company, Room 48, 330 Pine Street, San Francisco, California.

Any Stock upon which this Assessment shall remain unpaid on the 26th day of February, 1879, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on Wednesday, March 26th, 1879, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Trustees.

GEO. M. CONDEE, Sec'y.
Office, Room 48, 330 Pine Street, San Francisco, California

Mariposa Land and Mining Company of California.—Location of principal place of business, San Francisco, California. Location of works, Mariposa County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the tenth day of January, 1879, an assessment (No. 15) of One Dollar per share was levied upon the capital stock of the corporation, payable immediatelvin U. S. currency to the Secretary, at the office of the Company, Room 33, Nevada Block, No. 309 Montgomery St., San Francisco, Cal., or the Assistant Secretary at the office No. 9 Nassau St., New York, N. Y.

Any stock upon which this assessment shall remain unpaid the twelfth day of February, 1879, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on Wednesday, the twelfth day of March, 1879, to pay the delinquent assessment, together with cost of advertising and expenses of sale. By order of the Board of Directors. LEANDER LEAVITT, Sec'y.

Office, Room 33, Nevada Block, No. 309 Montgomery St., San Francisco,(Cal.

Office Wide Awake Prospecting and Mining Company.—No. 232 Sutter Street, San Francisco, Cal., February 1st, 1879. Location of works, Picket-Post, Pinal County, Arizona.

Notice is hereby given that at a meeting of the Board of Directors, held on the first day of February, 1879, an assessment (No. 6) of four cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin to the Secretary, at the office of the Company, Room 2, No. 232 Sutter Street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the first day of March, 1879, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Saturday, the fifth day of April, 1879, to pay the delinquent assessment, together with the cost of advertising and the expenses of sale. By order of the Board of Directors. C. HILDEBRANDT, Secretary.

Summit Mining Company.—Location of principal place of business, San Francisco, California. Location of works, Mineral Point Mining District, Pinmas County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the fourth day of February, A. D., 1879, an assessment (No. 7) of five cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the Company, 318 Pine street, San Francisco.

Any stock upon which this assessment shall remain unpaid on the eleventh (11th) day of March, A. D., 1879, will be deliuquent, and advertised for sale at public auction, and unless payment is made before, will be sold on the Tuesday, the eighth day of April, A. D., 1879, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

GOOD LAND
IN A
FAVORABLE LOCATION,
GUARANTEEING
Sure Crops Every Year.

The Reading Ranch,

In the Upper Sacramento Valley, originally embracing over 26,000 acres of

Choice Grain, Orchard and Pasture Land,

Is now offered for sale at low prices and on favorable terms of payment,

In Sub-Divisions to Suit Purchasers.

The ranch was selected at an early day by Major P. B. Reading, one of the largest pioneer and owners in California. It is situated on the west side of the Sacramento River and extends some 20 miles along its bank.

The average rainfall is about 30 inches per annum, and crops have never been known to fail from drouth.

The climate is very healthful and comparatively desirable. The near proximity of high mountain peaks gives cool nights during the "heated terms" which occur in our California summers.

Soft well water—remarkably sweet, pure and healthy—is obtainable at a depth of from 15 to 35 feet.

Wood is plentiful and easy to get.

Figs, Grapes, Peaches, Prunes, Almonds, English Walnuts, Oranges and other temperate and semi-tropical fruits can be raised with success on most of the tract. Also, Vegetables, Corn and all other cereals ordinarily grown in the State.

A considerable amount of the rich bottom land has already been cultivated.

Deep Soil With Lasting Qualities.

The soil throughout the tilled portions of the ranch proves to be of great depth and enduring in its good qualities. It is quite free from foul growths. The virgin soil among the large oak trees on the bottom land is easily broken up and cultivated.

The California and Oregon railroad traverses nearly the entire length of the tract. There are several sections, stations and switches, besides depots at the towns of Anderson and Reading—all of which are located within the limits of the ranch.

Land suitable for settlers in colonies can be obtained on good terms.

Are offered for sale in Reading, situated on the Sacramento River, at the present terminus of the railroad. It is the converging and distributing point for large, prosperous mining and agricultural districts in Northern California and Southern Oregon. Also, lots in the town of Anderson, situated more centrally on the ranch. Lots in both these towns are offered at a bargain, for the purpose of building up the towns and facilitating settlement of the ranch.

Purchasers are invited to come and see the lands before buying here or elsewhere. Apply on the ranch, to the proprietor,

The Strongeet Barrow Made. These Barrows are made by Superior Workmen, and of the best material. All sizes kept constantly on hand.

Lap-Welded Pipe, all Sizes, from Three to Six Inches. Artesian Well Pipe. Also, Galvanized Iron Boilers, from Twenty-five to One Hundred Gallons..

Iron Cut, Punched, and Formed for making pipe on ground, where required. All kinds of tools supplied for making pipe. Estimates given when required. Are prepared for coating all size of pipes with a composition of Coal Tar and Asphaltum.

Office and Manufactory, 130 BEALE STREET, San Francisco, Cal.

Ingersoll Rock Drills.

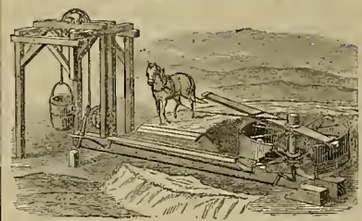
In use in the largest and best Mines of the Coast.

HAS AUTOMATIC FEED.

Has less Repairs.

Is Lighter and more Easily Adjusted than any other Drill.

Our DRY AIR COMPRESSORS are the most Economical Compressors in the Market.



MINERS' HORSE-POWER.

This Power is especially adapted to working mines, hoisting coal or building material, etc. It will do the work of a Steam Engine with one-tenth the expense. One Horse can easily hoist over 1,000 pounds at a depth of 500 feet.

The Power is mainly built of wrought iron, and cannot be affected by exposure. The hoisting drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

Fine Engraving.

The Engraving Bureau belonging to the office of this journal is prepared to design and engrave all kinds of Wood Cuts for illustrating newspapers, books, catalogues, cards, circulars, advertisements, labels, badges, seals, etc., in the best style of the art. Our portraits and illustrations of machinery, buildings and landscapes, are superior. Good engravings can be made from paintings, lithographs, steel and copper plate prints, photographs, models, patent office or other drawings. We have a photographic department and the best of machinery for producing accurate and perfect work at the lowest prices. Original maps, charts, and diagrams are made by our NEW PHOTO-RELIEF PROCESS at greatly reduced rates. By the same process copies can be cheaply and quickly produced of printed cuts, in *fac simile*, or they can be enlarged or reduced with equal facility.

Any hand writing in perfectly black ink on clear white paper for manuscript letters or circulars, will be accurately reproduced in metal plates suitable for common printing. Also, *fac simile* signatures, monograms, sheet music, etc. We excel in trade cuts and matched plates for combination color printing. With a large business, long established, and every facility for improvement, we can guarantee more than ordinary satisfaction to all of our patrons. All interested are invited to send for or call and see specimens and obtain prices.

Orders for electrotypes, stereotypes, steel and copper plates, lithographing, stamps and seal presses executed at low rates.

This paper is printed with Ink furnished by Chas. Eneu Johnson & Co., 509 South 10th St., Philadelphia & 59 Gold St., N. Y.

CARDNERS'
Celebrated
Governor
These Steam Governors have long been known as THE BEST, and as lately Improved and Perfected, they have no Rival.

THE SAFETY STOP
On these Governors is alone worth double the price of the Governor. We have sold over six hundred, and
Never one has Failed.
They are sold at the same price (or less) as ordinary Governors. Send for Circular.
BERRY & PLACE,

PATENT DETACHABLE TOOTH SAWS,
Manfuactory, 17 & 19 Fremont St., S. F.

Paul's Dry Amalgamating
BARREL PROCESS.

This is the most perfect of all systems for amalgamating the precious metals—more especially gold, for which it is absolutely perfect, the per cent. of metal obtainable being only governed by the fineness of reduction of ore. It will gather the flour gold with the same readiness as the coarse. The machinery and operation is simple and practical—not requiring skilled labor. Its efficiency is verified by mills in practical operation. I will contract for mills of 10, 20, or 50-ton capacity per 24 hours. Pamphlets, explaining the process more fully, forwarded on receipt of address. For further particulars apply to
ALMARIN B. PAUL,
Room 20, Safe Deposit Building, San Francisco.

MINING AND SCIENTIFIC PRESS.

An Illustrated Journal of Mining, Popular Science and General News.

BY DEWEY & CO., Publishers. SAN FRANCISCO, SATURDAY, FEBRUARY 15, 1879. VOLUME XXXVIII Number 7.

Smyth's Tree Feller.

Wm. H. Smyth, of this city, hae recently patented through the MINING AND SCIENTIFIC PRESS Patent Agency, an improved portahle sawiug machine and treo feller, the application of which is shown in the engravings on this page. The machiuc is intended not only to cut down treee, hut also to reduce the felled logs to convenisnt lengths for any purposc desired.

The reciprocating saw has a connecting rod uniting it with a cross head moving upon or hetween suitahle guides. These guides are loosely united at the rear end with the driving axle, so that they move ahout it as a center as the saw makss its cut. The driving crank is formed on this axle hetwoen the guides and is connected with the cross head hy a connecting rnd or pitman. In connection with the device a simple hut novel feeding apparatus is used which operates to feed the saw forward into the cut at each revolution of the crank and recipрocation nf the saw. The whole is mounted on a frame and provided with holding clamps or dogs so that it may easily hc attached to the tree or log in desired position to eut either horizontally or vertically. The mechanism is adjustahly conneeted with the driving powsr so as to hs moved from one tree or point to another without dieturhing the power.

The dogs hold the carriage firmly to the trce or log, when they are driven into the wood, so there is no motion to the carriage or frame. When the apparatus is used on fallen logs the short arms or dogs ars sccured helow and ths larger nnss on top.

The powcr is applied to this machine prefcrably hy a chain or rope passing over a pulley from the power wheel. The powsr may hs derived from an engine, horse or other convenient source, and may he connected ovcr uneven ground by tumhling rods, therehy enabling the machine to cut all the trees or logs inside of a cirele nf say 150 fcet, without moving the power. The application of the power is plainly shown in the engraviug.

The saw is only fed on the back stroke, and ths feed is variable, suitable arrangements heing made for regulating it at will.

The feeding of the saw is accomplished hy two inclined hars or plates on the saw har which are raised or lowcred hy means of thumh screws. These incliued hars operats two rack hars which in turn movs two worm gears which engage with the teeth on ths segment, causing ths guide hars and saw to move the required distance for proper feed. By hringing the inclined hars closer together or farther apart the amount of feed is rsgulated with great nicety; and once set the fsed will remain the same and hs automatic.

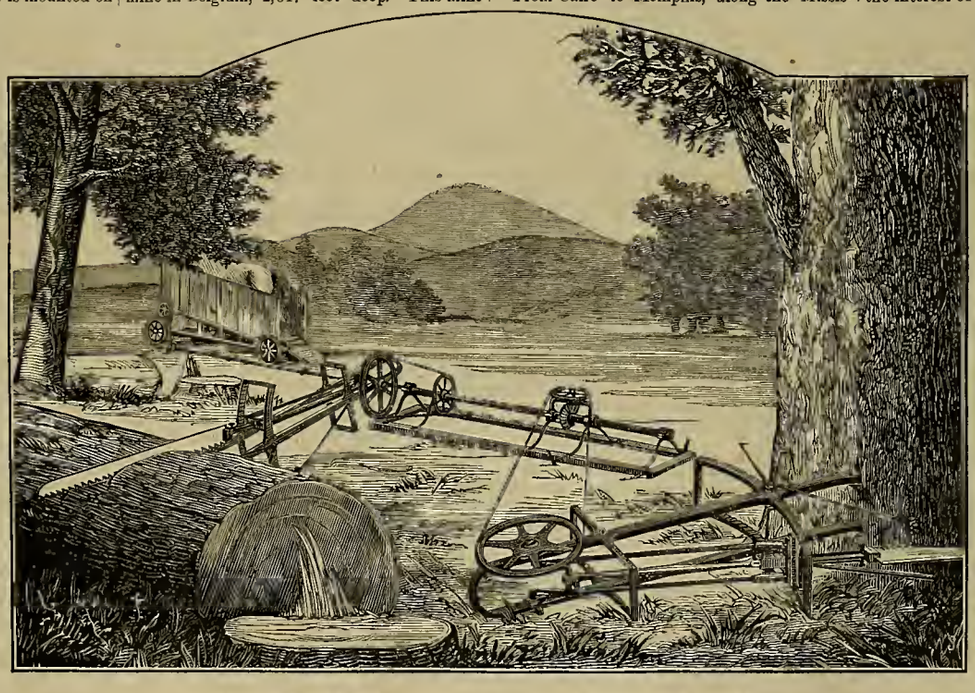
This device is ahle to cut the trees so closs to the ground that a header can pass over the stumps. In fact it can cut even with the surface or below it, if desired. Half a dozen or more saws can he run from the same central power, provided thers is power enough.

It will he seen that when it is necessary to cut a long fallen tree into sections or short logs, the driving wheel can he slid along the shaft to the extent of the frame where a hlank tumhling rod may he inserted, therehy moving the frame the length of the rod. By adding other lengths the carriage may be carried the whole length of a large tree without having to change or move the power.

This whole machine only weighs 150 pounds, and two men cau move it ahout with easc. One of the machiues can he easily run with a single horse-power, and the labor of felliug and sawing trees performed by horss iustead of manpower. The saw runs at a spced of ahout 125 strokes per minute, and cau therefore do great execution. Trees eight feet in diamcter havs been sawed with tho machine without difficulty.

In pine and redwood timber this will do very good work, and men furnishing logs to mills ou coutract will it of find the greatest ahility. In cutting logs for mincs, and getting out railroad fuel, its uso will be a great saviug.

The iuventor, Mr. William H. Smyth, can be addressed P. O. box 1308, this city, for further information.



SMYTH'S TREE FELLING AND LOG SAWING MACHINE.

THE DEEP MINES OF THE WORLD.—In reply to the letter of Mr. H. Musgrove and others, Lake City, Colorado, inquiring as to the dspth of tho deepest mins now heing worked in the world, we may say, this distinction prohably helongs to the Adalhert mine, Austria, in which the workings are prohahly carrisd on through a perpendicular shaft 1,000 meters—3,280 feet deep. This is a lead-silver mine, and has heen worked many years. The next deepest mine on the continent of Europe is the Vivisrs coal mine in Belgium, 2,847 feet deep. This mine was explored to a depth of 3,586 feet, hut no coal having been found, all helow the 2,847 level has since heen ahandoned. The Dunkirk colliery, Lancashire, England, has heen opened to a depth of 2,824 feet, and the Rossbridge colliery, same locality, to a depth of 2,458 feet, these heing the deepest mines yet opsned in Great Britain. Ths Yellow Jacket is ths deepest mine opened on the Comstock lode, its lowest level heing now ahout 2,500 feet helow the surface at the mouth of the main shaft, and 2,933 fest helow the Gould & Curry croppings, the datum line for the Comstock mines. The Savags, we helieve, stands second on the list, and the Imperial third, both of these mines heing very nearly as decp as the Yellow Jacket. We hope soon to he ahle to give these figurcs with exactness, adding somo further data relative to the deep explorations now in progress on the Comstock, with perhaps also fuller information in regard to the deep mines of Great Britain and Europe, their history, production, etc.

CITIZENS of Omaha and vicinity have shipped a car-load of flour to Glasgow, Scotland, for the relief of the unemployed and distressed in that city. Free transportation was furnished to New York hy the railroad, and hy the Anchor line eteamships thence to Scotland.

Earthquakes Here and Elsewhere.

The old, commonly accepted opinion that earthquakes wsre confined to ths Pacific coast of the United Statss is fast hecoming changed, on account of frequent ocourrence of similar disturhances in other parts of the country. Ths Pacific coast, in fact, has for ovsr 10 ysars heen free from all hut ths slightsst ehocks, while it is noticsahle that the hsavisr Eastern sarthquakes date from that tims to the prssant. The last, that of Nov. 18th, 1878, occurred in ths Mississippi valley, and traveled over an area of fully 150,000 square miles. According to Prof. Niphsr's report to the St. Louis Academy of Science, the region disturhed forms an ellipss, the major axis of which extends from Lsavenworth, Kansas, to Tuscaloosa, Ala., a distance of over 600 miles. The minor axis extends from nsar Clarksville, Ark., to a point midway between Cairo, Ill., and St. Louis, a distance of 300 miles. How far south the disturhance extended has not been determined with accuracy.

From Cairo to Memphis, along the Mississippi, ths action was most severe and heavy. Here the movement of the walls of huildings was plainly perceptihle, and the creaking of the joints of stroug frame houses distinctly heard. At Ironton the shock was less severe, though owners of hrick houses found some cause for alarm. Between Glasgow and Lexington, on the Missouri, the shock was intense enough to awaken many people, who thought that a heavy wind-storm was in progress The shock was first felt at Glasgow, at 11:23 P. M. (St. Louis time). It traveled rapidly along the axis of the ellipse, reaching Cairo at 11:48 and Msmphis at 11:50. Up ths river it gradually hecams less violent. It was perceptihle at Little Rock, Ark., though at Clarksville, 35 miles ahove, it had hecome too faint to be perceived.

THE WAY IT GOES.—In Joues county, Iowa, two farmers had a qnarrel ahout 14 fence rails, alleged to he worth $1.40. They hired two lawyers and went to law, hammer and tongs. After a long contest the plaintiff got a verdict of one cent, the cost to tho county was $60 and the lawycrs had pocketed $324. The farmers then elected the lawyers to the Legislature.

COAL oil has been discovered near Yreka.

Mining and Farming.

As this country is likely soon to rsceive a conciderable immigration from Europe, and there are already a good many msn in ths Eastsrn States out of employment, it may he well to say to these various classes of lahorers that the mining regions west of the Rocky Mountains are far from hsing crowded. To the right kind of men—ths hardy, resolutc and industrioue—thsre ars excellsnt chances for getting ahead in svery one of the Pacific States and Territoriee. It is rathsr a rough field, hut one full of good opportunities to those qualified tn maks them thoroughly available. As a pursuit, mining is not, like farming, one that can hs easily crowded, nor is it one that ie ever without a remunerative markst for its products. With gold and silvsr there occurs nsither glut nor dspreciation of price. "Mining," says the Auhurn *Argus*, "is the only field not yet in great part explored, the only one the product of which conflicts with the interest of no man, hut rathsr, as it makes tho world richsr, enhances the welfare of all the world." It is mining, certainly, that has chiefly given wealth and prominencs tn this coast. This industry is not now the mere hazard nf 30 years ago. It has become a sciencs among us, and we can predict with much certainty what the profit on the operations will he.

This fisld is limitless, and cvsry hlast that is tamped, every shovsl of gravsl that is lifted, aids ths farmer and the mechanic hundreds of miles away, for it opsns to them a market for their products and lahor.

In view of ths aid this industry affords all others, the Government should open cheap communication with the mines. Rich men everywhere should turn to them and make work for thoss who need it. Our Legislaturs should adopt a hroad, liheral policy with respect to our mines. Thsy must protect the capitalists from the people, and the people from the capitalists. The capitalists—for unless laws arc passsd freeing the miner from ruinous taxation and capricious intsrference capitalists will not invest tl.eir money sither for working old or for opening up new ground.

The lahorsrs otherwise will he ground down by the power and speculations of wealth. But recognizing all thess things, and also that it is through speculation, and not the actual working and devslopment of the mines, that money is lost as it has been in the Comstock and many other great mines, legislators will see that this is the most plausihle, if not the only solution of the social prohlem, and use their power toward making laws which will recognizs mining as the first industry of the State and coast; that with mining prospcrous, all other industries will flourish, and that in stimulating and accelerating the growth of mining they are indirectly contrihuting to thc welfare of svery department of business.

THE "Agricultural Report," just issued, gives the average pricè of the cotton crop for the whole country at 8¼ cents per pound. Value of the orop for 1878, $194,700,000. Average price of tohacco, 5, 6 and 10 cents per pound. Total crop for 1878, estimated at 393,000,000 pounds, worth $22,000,000.

"RED" FRANK WHEELER, a jovial, popular man, well known on the Comstock and throughout most of the mining camps in Nevada, is dead.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—EDS.

Steam Plowing Again.

EDITORS PRESS:—Ohserving a letter in the PRESS of February 1st, 1879, from a "suhscriber," in relation to steam plowing, I can inform him from a very extended experience that an engine for plowing, which would only weigh 2,500 pounds, would not he an economical machine, and would not do the work whicb he estimates. Our plowing traction eugiue weigbed near eleven tons, and iustead of sinking in land fit to plow, it plowed land nine inches deep and turned and run hack on the plowed land. On Haggin & Carr's ranch in Keru conuty, we plowed three acres an hour continuously for days in the sandy loam of that region. We used 12 12-inch plows in one gang, tearing np a width of 13 feet of new grounds, with one engineer, one fireman, and one plowman or man to look after the plows. OLIVER HYDE.

Vallejo, Cal., Feb.

The Cone-bearers, or Evergreen Trees of California.—No. 4.

[Written for the PRESS by J. G. LEMMON.]

Fir and Tamarack,

The last paper discussed the spruce family, closely allied to the fir, with which, as shown, it has often becn united or more or less confounded. But the distinctions are tbere given witb Dr. Eugelmann's *auf clarung* of the whole matter. It remaiue now for us to correct our vernacular and to apply the colloquial names to the proper trees.

Fir Family.

The firs have generally a very symmetrical, conical or fusiform outline, the limbs or whorls like immeuse fane, form borizontal strata in a diminishing series to the top. Timher soft and generally worthless. The cones borne by tbe uppermost limbs are upright, of numerous close-set scales and bracts, wbich fall away at maturity, leaving the core, or rachis, etanding. Leaves of lower limbs in two ranks; six species in California. Tbe geueric name, *Abies*, is a corruption of "apios," a pear.

1. *Abies sub-alpina*, Engel., variety, *fallax* Engel., the "*Picea amabilis*," prohably, of Douglas; the "Pumpkin Pine" of Oregon Cascades, and probably reaching down to California; trees 60 to 100 feet high; timher very soft; wortbless; bark thin, pale, smooth; cones elliptical, oblate, eix inches long; leaves glaucous-green, two inches long, notched on tbe lower eterile branches, pointed on the fertile.

2. *Abies nobilis*, Doug., "Red Silver fir" of tbe Shasta region. Stately trees 200 feet bigh; timber harder, valuable; bark thick, cinnamon brown or reddish; cones elliptical, oblate, six to eigbt iuches long; bracts protruding one inch and curved downward, clothiug tbe cone witb a beautiful mantle.

3. *Abies magnifica*, Murray, "Red Silver fir" of tbe Sierra; "*Picea amabilis*" of hotanists and collectors. This magnificent Queen of tbe Sierras, at altitudes of 7,000 to 10,000 feet generally attaine to 150 to 200 feet, witb a diameter of 5 to 8 feet; often mucb loftier and from 10 to 14 feet in diameter. Timber valuable; bark very thick, and reddisb witbin; cones elliptical, oblate, 6 to 8 inches long; bracts concealed; leaves all pointed, not twisted at base; striped beneatb witb four wbite silvery lines; hence the vernacular name of "Silver fir." The color of the bark wben cut gives it the name of "Red fir." Travelers aver tbat no fir on tbe globe exceeds this California species in magnificance and symmetry. One has but to visit a grove of these stately trees on bigh plateaus of the Sierra—notably near Webber lake—to receive impressions of majeety, grace and perfection that will eerve for mental enjoyment through life.

4. *Abies grandis*, Doug. "White Silver fir" of the northern coast region. A very tall tree, 200 to 300 feet high, but seldom over four feet in diameter. Timher, white, soft and coarse; bark, smooth and grayish; cones, cylindrical and two to four inches long; leaves, glossy green, marked beneath with two silvery lines, strongly grooved ahove and notcbed at apex, and one to two inches long.

5. *Abies concolor*, Engel. "White fir;" common on the Rocky mountains, from the bigher peaks of Mexico to Alaska, and throughout tbe Sierra at elevations of 3,000 to 7,000 feet. This etately tree yields only to *Abies magnifica* in etateliness and symmetry when young, and becomes still less striking in age. Timber less valuable, being softer and also scentless; is prized for butter boxes, meat barrels, etc.; hark, ashy gray outside, darker within and deeply fissured in old trees; cones, cylindrical and two to four inches long; leaves, longer than the preceding, two to three inches, twisted at base half way round and mostly blunt. Tbis species bas been generally mistaken for *Abies grandis*.

6. *Abies bracteata*, Doug. "Bracted fir" of a limited region on the Santa Lucia mountains in Monterey couuty. A little known tree, said to be "steeple-shaped, 100 to 120 feet high, with a diameter of two to four feet, unsurpassed in all the merits that the most appreciative could deeire." Coues, elliptical, oblate, three inches long, of few appressed, emooth, glaucous scales, between which protrude one to two inches of the mid-ribs of the hracts, curving upward so as to vail the cone from sight and reminding of teasel hurs; leaves, two inches long, flat, rigid, acute linear-lanceolate, of firm texture and twisted at hase half way round.

"Poor Amabilis."

This concludes the list of firs to he met with in California. It will be noticed that no species is here described nnder the Douglasian name of Amahilis. Alas, poor Amahilis! The "lovely fir" of Douglas has had a fearful tossing about for 45 years, and now is holdly dropped altogethcr, as being the best way to end the confusion caused by the paucity of the material gathered—only a few leaves and one cone (since lost)—by the venerable botanist and collector, David Douglas, wbo, after ecnding bis collections home, met witb a violent deatb on the Sandwich Islands.

There is still much uncertainty and discussion relative to tbe firs. The late visit of Hooker and Gray to California enabled these great masters to collect and compare much data, upon which they will soon report.

They now think that couuecting forms may show the union of *A. nobilis* and *A. magnifica* in one epecies, wbich must bear the name of *nobilis*, of wbicb *magnifica* would he tbe soutb-ern, sbort-bracted variety.

Tamarack Family.

The fourtb and last genus of the trihe *Abietinæ* is hut sparsely represented in California, barely reaching the northern limit from Oregon, where it is very abundant. Plainly distinguisbed hy its leaves, heing deciduous (falling annually), slender, short, and in fascicles of 2 to 20 on tbe ends of yearling branches. Two species in California. The scientific name *Larix* is an old Greek word applied to this tree, corrupted by the Euglish into "Larch." Cones small, depcuding.

1. *Larix accidentalis*, Nutt. "Western tamarack;" on tbe bigb plateaus of tbe Coast range of Oregon; often 250 feet high and five feet in diameter; frequently 200 feet to the lowest limhs; free to split and very strong and durable, beuce highly prized.

2. *Larix Lyallii*, Parle. "Lyall's larcb" of the Cascade mountains of Oregon; but little known.

This concludes the description of the four principal genera of the conifers, comprising the most of our California forcsts.

[To be Continucd.]

Boiler Incrustations.

[Written for the PRESS by R. GRIMSHAW.]

One of the principal tronbles in engiueering practice is tbe deposits of mineral incrustations on the walls of boilers. The matters forming tbese ecales are generally limey salts, such as carbonate or sulphate of lime, wbich are less soluble in hot water thau in cold. Thus water at 20° C. (68° F.) dissolves a little less than one-quarter per ceut. of its weigbt of sulphate of lime; wbile at 100° C. (212° F.) it takes up a little less than 5-23%; that is, 1-30% less than at 20° C. It results then that when water charged witb sulpbate of lime is heated from 20° to 200° C., it must deposit 1-30% of its weight of this salt; that is, one pound for every 3,000 pounds of water. If the water is not only beated to 100° C., but evaporated at 100° C., it must deposit all tbe lime it contains; that is, one-quarter of a pound of scale for eacb 100 pounds of water, or one pound for every 400 pounds of water.

Now as a square meter of heating surface evaporatee 20 kilograms of water per hour, and as tbe deposits are generally on the beating surface only, it follows tbat eacb square meter ought to have 1-20 kilog. per hour (or 18 kilog. per month) deposited on it, making a scale about 8 mm. thick.

It is useless to repeat bow much a stony lining 8 mm. thick will lessen the condnctive power of a plate and thus waste fuel, retard steaming and burn the ebeet.

This deposit of carhonate of lime is generally because this salt is only soluble in water containing carbonic acid gas. "Boiling ont" this gas causes tbe water to drop the carhonate.

Tbere are any number of processes to combat boiler incrustation. Most of them, declared infallible by tbeir inventors or discoverers, present beside their advantages so many objections that tbe remedy is frequently worse than the disease—as where tbe engines are ruined by foreign matter carried over by the steam, or the plates corroded by tbeir action. The details of the behavior of almost every substance tested, may be found in Van den Corput's memoirs, in vol. xxxi. of the *Bulletin du Musee de l'Industrie;* we ehall solely generalize bere.

Tbeir action is either mecbanical, physical or chemical. Tbose whicb act mechanically tend to cause the deposits to move so as not to adhere. Of these we may name pehbles, metallic halls, spun glass, etc., all proposed to be put in the bottom of the boiler. The glass is particularly dangerous as causing rapid wear of the engines after it is carried over hy the steam. Little fagots of wooden sticks are mucb safer, but unbappily they do not gatber mucb incrustation.

"Agitating" devices are of little use—the water in a boiler ie in a higb etate of agitation anybow, over the beating surface. Among materials acting physically are clay, potato etarch, wood sawdust and dye liquors; these act as *interposants*, enveloping tbe particles of earthy deposits, and preventing them from agglomerating in a hard mass; they can hence be readily blown off at the proper cocks. Of these, clay only increases the weight of the muddy deposits. Potato starch (ground potatoes) is better; throwing it in from time to time.

Another remarkahle interposant is a paint composed of graphite, tallow, powdered charcoal and tar, applied to the inner walls. The deposits will not etick to this; hut it has this objection, that it must be renewed every 15 days or so, and this takes a long time (sometimes two days) and thus necessitates stoppage of steam supply or the use of reserve boilers. Tbe same result is obtained by greasing the walls of the boiler; but tbis often causss foaming or else corrosion of the plates. Tar and mineral oils are best for this purpose.

The chemical agents proposed, as carhonate of soda, sal ammonia, alum, etc., transform the slightly eoluble salts into salts either soluble or completely insoluble, and depositing at once without adbesion. Tbe results obtained are neitber thorough nor constaut, while there is also to be feared corrosion of the sbeets by acids set free in these reactions.

Certain substances, as molasses, beer malt, beet pulp, etc, act physically as interposants, and also chemically by the sugar tbey contain, and wbich facilitates the eolubility of moet lime ealts. Most of these cause foaming in the boilers, fouling the gauge-glasses or gumming of the valves of the engine.

It is mucb best to precipitate tbe limey salts before the water is fed into the boiler. A very simple way is to have a large supply tank and to inject into the water it contains, a jet of steam which will cause it to deposit most of its limey compounds.

There is much needed a simple and inexpensive filter and precipitator, wbicb may serve at the samo time as a feed-heater.

Your Salt.

John Barton, of Alameda, is President of a salt manufacturing establishment at Mt. Eden, on San Francisco bay, 22 miles from San Francisco, whicb is locally known as tbe

Union Pacific Salt Works.

They were establisbcd some 11 years ago ou an island formed by the bay aud what are known as Eden and Union City crceks. This island comprises about 1,200 acres, aud is eutirely owned by the company. It is divided hy dykes into immense reservoirs, wbich are numhered, No. 1 heing ncarest the bay. Upon tbe termination of the winter rains, and as soon as the weather becomes settled, operations at the mauufactory commence. From 60 to 80 men are employed in the yards, they beiug uuder charge of a foreman, Mr. A. B. Winegar, who has occupied this position for 11 years, and is considered one of the most experienced and capable salt-makers in the United States. The

Reservoirs

Are put in thorough repair, levees overhauled, and everything put iu readiness, and sea-water is tben let into reservoir No. 1, through uumerous small gates. This reservoir is 300 acres in extent. When this "catch" bas remained in the reservoir from 20 days to four weeks, it is then discharged into rcservoir No. 2, 250 acres in extent, aud a fresh eupply let into No. 1. The first "catcb" is then, after remaining in No. 2 about tbe same length of time, transferred into No. 3, No. 2 being filled again from No. 1, and No. 1 from the ocean. In the same manner the brine is discbarged into reservoir No. 3, 100 acres in extent, whence it is emptied into the

Liming Ponds,

Nos. 4 and 5, where the lime is precipitated to the bottom. When the brine bas reached a strength of 17° (hydrometer) all tbe lime has crystallized at tbe bottom of the pond, and the liquid then begine to crystallize salt. This process of removiug the impurities is only practiced at theso works, and is one of the reasons of the superior quality of their salt. Iu hoiled salts, the rapid and unnatural method of crystallization forces the lime to settle witb the salt, and thus affects its purity. When the liquid is known to bave discharged its lime it is emptied into the numerous

Crystallizing Ponds,

As occasion may require. For the finer grades of salt these crystallizing ponds have wooden floors, and when the deposit is completed these floors are "raked," tbe salt in large crystals being scraped into heaps, shoveled into baskets, transferred on small hand cars to the edge of the yard, where it is dumped into huge pyramids, whence it is sacked and transferred to the company's mills on Sacramento etreet, where it is dried, ground into various grades, and finally prepared for the market. The salt, from the time its manufacture is commenced until it is delivered to the purchaser, is

Handled

Exclusively by the company. It is transported by their own schooners, bauled by tbeir own drays, put np in sacks of their own manufacture, and its hraud printed tbereon by their own printing press. This complete business arrangement is due to the sagacity of Mr. Barton, who has given the business his individual attention from the time he first became identified with it, some 16 years ago, until the present time, wben it stands without a rival in size and amount of business.

The works have a capacity of 20,000 tons per season, and tbeir average annual production is 12,000 tons.

For a description of the works we are indebted to tbe editor of the Alameda *Argus*.

How Money is Made from Copper in Yuba County.

It is a very simple process. Copper sulphuret is roasted to sulphate, leached and precipitated with iron. We are indehted for tbe following particulars to the Grass Valley *Union:*

The entire improvements made npon the Spenceville property have cost nearly $100,000, and as an evidence that the enterprise has heen profitahle is tbe fact tbat no assessments have hcen levied npon the stock for two years. The

Capacity

Of tbe works for the last six months bas averaged 25 tons of cement copper per month, which required tbe monthly nse of about 500 tons of ore. Tbe present product is 30 tons per month, and by next spring it will reach 60. The gross product of eacb ton of ore workcd is about $12.50, and net profit about $8.25 per ton. With the product of 60 tons of copper psr month, worth $15,000, the profit will be $10,000 at present prices of 17 cents per pound for the copper in the San Francisco market. The regular monthly expense account is between $6,000 and $7,000, and the number of employees is 12 men in the mine and 13 on the enrface.

Reduction.

The old ehed contains 12 leaching vats and the new one, standing directly below the new ore shed. will contain 20. The reduction works coutain four revolving cylinders, and two more are to be put up. A small engine furnishes all the power necessary to drive the machinery. From the hoisting works the ore hereafter will be conveyed to the top of the hill by a railroad, which is now in use. The cars are loaded from ore chutes, and drawu to the top of tbe bill by a stationary engine.

During the present season tbe company have made extensive

Additions

To their works to increase the capacity for production, and for economy and expedition in handling the ores. Tbe ore shed which has heen used until this time is 350 feet in length hy 60 feet in width.

It bolds 4,000 tons of ore arranged iu two lines of piles of 100 tons each. This has heen supplemented hy a uew shed, built on the top of the hill above the miue, whicb ie 500 feet long, and will contaiu 3,000 tons arrayed in piles in a singlo line. And it is intended further to extend this shed, and do away with usiug the old shed at the foot of the hill, because in manipulating the ores it is important to have all tbe other works below where the roasting is done, as everything has to work down hill, from the ore piles to the leacbing vats, tben to the receiving vat, and lastly to ths reduction works. Thc

Product Increases

From month to month without an increase of expense, for tbis reason: In working of the ores by tbe leaching process ouly ahout two-tbirds of the copper is ohtained, hut the waste pile is continually furnishing a large amount of solution that is utilized. The ground where the waste pile is accumulating is first covered with a sheeting of felting and asphaltum; the waste is there dumped aud water is freely thrown upon it witb bose; this percolates througb the pile, and it is caugbt in eluices and conveyed to the reduction works, where it is worked into copper. This waste pile will continue to increase from year to year, and will furnish one-third of all the product for the mere lahor of taking up the solution as it drains from tbe pile. Thus it will be seen that the waste pile is to be a permanent source of profit, and nonc of it goes to loss. During the last 12 months the production has not only met all expenses, hut has carried the improvements now approaching completion.

A GOLD MINING EXHIBITION.—William I. Marshall, a Montanian from Fitchhurg, Mass., lectured recently at the Cooper Union, N. Y., upon tbe "Yellowstone National Park," and in the course of the lecture, described the stats and process of gold mines and gold mining in America. Many who sougbt admission at the door were turned away. Upon the platform bebind the speaker, was a large screen, upon wbich views of mines and the mining conntry were shown by the magic lantern. On a etand on one side was a fac-simile of the 150-pound Australian gold nugget, which sold for $50,000. Mr. Marsball showed, by means of utensils whicb he had upon the stage, tbe manner of cradliug and washing with a pan whicb gold miners employ. Speakiug of the actual scarcity of gold, he said that the whole world's product of ages of time and acres and acres of mining, if melted down and run without alloy into a eolid mass, would not make a cuhe mcasuring 29 feet on a side, though the estimated value of all the gold coin, bullion and jewelry is $6,500,000,000.

FUEL FROM WASTE.—From the debris of the coal mines, France makes annually 700,000 tons of excellent fuel, and Belgium 500,000 tons. In England, where there is not so ninch waste in coal mining, and where coal is much cheaper, the manufacture of artificial fuel is only about 200,000 tons a year. Germany makes fuel, for the most part, from peat and similar eartbs.

SMOKE is not, as many persons imagine, lighter than air; it is, however, carried up hy the heatsd air, wbich being lighter than tbe surrounding atmosphere, is pressed upward. Smoke ascends because it is intermixed with vapors, gases and warm air.

Mechanical Progress.

Cold-Rolled Shafting.

An experience of many years proves more and more the importance of good shafting for the transmission of power. Whether gearing is attached to the same, as thus far has been the prevalent custom in England, or, what have been proved to be better, pulleys and belts, as has been the custom in the United States, and bid fair to be accepted all over the world—in any case, the shafting must be good, true, and strong, free from oscillation, flexion, or danger of breaking, twisting, or giving out in any manner; hence at the present day special attention is given to furnishing manufacturers with superior shafting, for which the demand has been continually increasing in proportion as mechanics have discovered its importance.

The best shafting is undoubtedly that which has been finished by cold rolling, by which the metal is condensed and its strength increased, while it becomes remarkably straight, true, and uniform in size; also, its surface represents a highly polished appearance.

The superiority of such shafting was shown by Major Wade, of the United States Ordnance Department, in 1860. He found by practical tests that bars of puddled and charcoal bloom iron, rolled hot in the process of manufacture, were increased in strength by the cold rolling, a process which at that time had been patented by Lauth. The results of the tests were as follows: Transverse strain for permanent set increase in strength, 162½%; torsional strain to produce permanent set, increase 130%; compressional strains to produce permanent act, increase 95%; ultimate strength under tension, increase 72%; hardness, increase 50%. Sir William Fairbairn found an increase of 50½%, comparing ordinary bars of a given size with similar bars reduced in size by cold rolling.

A similar series of trials made by the Franklin Institute of Philadelphia, showed an increase of ultimate strength for the cold-rolled shafting of 61% in tension, and 97% in compression. It is claimed that cold-rolled shafting has from 30% to 40% more effective strength than the same sizes of turned iron.

It is easy to comprehend the immense difference in effect when a shaft is finished by cutting the surface with a chisel on the lathe, or when, instead of this disintegrating operation, it is passed through rollers and the smooth and uniform surface is given to it by a powerful compression of the surface, and that in the latter case the density and strength must necessarily be much greater. If, incidentally, there is any porosity in the iron, the cutting on the lathe may lay it bare, while by cold rolling the pores will be closed up; it is, in short (to use common language), the difference in cutting away and squeezing together.

Cold-rolled shafting has begun to be generally appreciated; it is now used by locomotive and other engine builders, and by pump manufacturers, for piston-rods, pump-plungers, etc., without turning, except to make connections. It is also used to make pins for bridges. Cold-rolled iron is also used in preference to steel for the finger-bars and knife-backs of reapers and mowers, and for other special purposes.

Welding Fused Iron.

The difficulties which formerly stood in the way of the welding of iron obtained by fusion processes have been entirely overcome. Stated in broad and general terms, the welding power of iron rises and falls in the inverse ratio of its content of carbon; but the limits of its capacity for being welded are sooner reached than those of its malleability, and irons with a high content of carbon will not weld. The difficulty of welding diminishes in proportion to the ease with which fused iron can be obtained with a low content of carbon.

The question whether the metal obtained in the converter or the reverberatory furnace welds better has been carefully investigated, especially in Sweden. The conclusion has been arrived at that with a similar chemical composition, similar temperature, and similar working conditions, there is no difference. As a matter of practice, the rule is that the metal for heavy forgings is prepared in the reverberatory furnace, and that for lighter ones in the Bessemer converter. The process of dephosphorizing by oxides in the desilication gives the reverberatory furnace the preference at present, although the preference may not be a lasting one.

The uses of malleable iron have increased on the whole, owing to the more common employment of fusion-process irons, the freedom of which from cinder makes them more uniform in quality and trustworthy. Heavy pieces, many thousands of tons in weight, are no longer regarded as anything remarkable. The mechanical properties of the various irons made by fusion are so easily regulated to practical requirements, that there is no longer any limit to their use other than that set by cost. The extension given to the making of irons by fusion processes has also had the effect of raising metallurgy out of its former condition of empiricism, and demonstrating the necessity of scientific investigation. Ample proof of this was given at the late Paris exhibition. There was no well-ordered collection without its elaborately formulated analyses and tests, which for the most part showed a complete mastery of the scientific principles involved in them.—*Iron.*

Hints for Inventors.

The *Scientific American* calls the attention of inventive and practical men to the defects of locomotive boilers, and the advantages which might result from their improvements. It says: A locomotive boiler has three principal parts, all imperfect in greater or less degree. These are the fire-box, the tubes, and the smoke-box. The fire-box has rectangular walls, surrounded by water, except under the grate, and where the fire-door is placed. This is an arrangement necessitated by the requirements of science and not indicated by rules of utility or good construction. The flat form of the fire-box walls and of that part of the boiler which covers it, takes away from them strength of resistance, save what is given to each by the other by stays in immense number. Those must resist an enormous pressure, especially the roof of the fire-box, where it is not counteracted by any opposite pressure, and sometimes may amount to 200 tons.

This arrangement prevents proper cleaning of the outer walls of the fire-box and the inner walls of the boiler plates opposite. It is about the same thing where the tubes are; and these, rarely over two and one-half inches in diameter, are so numerous that it is as difficult to clean them exteriorly as it is to clean that portion of the boiler surrounding them.

The draft, urged by the jets of exhaust steam in the stack, is so strong that the air and gases in passing through the tubes at a high rate of speed drive with it a considerable quantity of fine dust, the residue of combustion of coke or other fuel; this dust scratches and cuts the tubes so as to necessitate their renewal. The dilatation and contraction of these tubes also cause leaks and repairs. The forced draft also costs dear in another way; because this steam jet creates a back pressure in the cylinders, frequently amounting to one-third the effective pressure. Further, the space left above the tubes and the smoke-box is so small as to reduce too much the proportion between the steam volume and the heating surface. It is also not unfrequent that the steam carries with it half its weight of water.

A Hand Loom Wanted.

The same journal says that there is a demand for a hand loom for amateurs' use. A correspondent writes: "We can get lathes and fret saws and printing presses and other machinery for the use of amateurs in abundance; but a compact, portable hand loom would be a novelty, of which it might, with some truth, be said that no house would be complete without it."

The number of people seeking industrial recreation is very large, and out of these a profitable clientage can be secured, no doubt, by whoever will offer them the novelty called for. It may pay some of our inventive readers to give the matter a little practical consideration.

Coating Metals with Platinum. — Mr. Dode, a Frenchman, has recently invented a process for covering iron with platinum. The iron is first coated with a preparation of lead and copper. It is then ready for the platinum composition, which is thus made: Ten parts of platinum are converted into chloride, mixed with five parts of ether, and permitted to evaporate in the open air. The residue is incorporated with a compound of 20 parts borate of lead, 11 parts of red lead, some oil of lavender, and 50 parts of amyle alcohol. Into this mixture the article to be coated is dipped, then allowed to dry in the air, and finally heated to a moderate temperature, in a muffle furnace. A practical demonstration of the *modus operandi* was recently given at the laboratory connected with the Mint and Bank of England, at which the ease and simplicity of the operation was fully seen and acknowledged; but as the invention is a recent one, the important element of time and wear to test his work is as yet wanting. The invention relates more particularly to the coating of articles of cast-iron, but is also applicable to the covering of other metals in order to preserve them from oxidation under the action of air, fire, or acid gases. The same process is applicable to glass. The processes hitherto known for the coating of metals have only imperfectly attained the object in view, inasmuch as the coverings of copper, nickel, silver, or tin, applied by immersion or with the aid of galvanism, are not adapted to prevent oxidation. Mr. Dode's invention consists in the application of platinum in such a state of division as to enable it to be employed as a preservative against the oxidation of metals, whereby a considerable saving is effected, as compared with the systems at present in use, and much greater efficiency is obtained.

Absorption of Carbonic Oxide by Living Organisms. — N. Grehant has experimented with mixtures of air and minute portions of carbonic oxide. He finds that a man or an animal, when compelled for half an hour to breathe an atmosphere containing only 1-779 of carbonic oxide, absorbs that gas in sufficient quantities to saturate about half the red globules of the blood, so that they become incapable of absorbing oxygen. In an atmosphere containing 1-1449 of carbonic oxide, about a quarter of the red globules are similarly saturated. These results are interesting and important in relation to physiology and hygiene.

Scientific Progress.

The Social Science Convention.

The annual meeting of the American Social Science Association was held in Boston, January 8th. The meeting was opened by the reading of a letter from the President, David A. Wells, explaining his absence and reviewing the progress and opportunities of social science. Never before in the history of the world have so many and so important questions—fiscal, economic, educational, sanitary, and moral—pressed themselves upon the attention of the public.

The steamship, the railroad, and the telegraph are breaking down the old and formidable barriers of nationalities, and, for the purpose of business, are making the whole world one country, a condition of things under which the great fundamental truth of modern political economy, that nations and individuals are alike benefited and never injured by the prosperity of their neighbors, will be more than ever manifested. All methods of production and exchanging are also undergoing modification, with the certain result, which no legislation can prevent, even if it were desirable that it should, of economizing labor and material, and the cheapening of production. During, and in consequence of these changes, and for years yet to come, there will be much of discomfort, and undoubtedly also of suffering, from the displacement of individuals from occupation and their readjustment in new positions or locations. Millions of capital now useful and returning an income to their possessors, are certain, in the no distant future, to be also made worthless, as the course of improvement requires that they shall be, in order that protection may be cheapened and made better. But the ultimate result will be undoubtedly greater abundance, less poverty, and a higher elevation of the race. To forecast the course of economic agencies and events; to help make the burden of disturbance and change in occupation less grievous to the people; to help overcome that moral inertia among the masses which greatly prevents them from helping themselves, and accomodating themselves with rapidity to the demands of progress, are all questions and problems pre-eminently within the domain of social science.

And if there is any advantage in associated efforts over individual and isolated effort, in the way of determining and disseminating truth, then, Mr. Wells concluded, the American Social Science Association has the largest of opportunities before it for future benefaction.

Much time was taken up in the reading of a paper by Mr. Geo. T. Angell, of Boston, which consisted of a tissue of extravagant assertions in regard to the adulterations of food, drinks, medicines, etc., entirely unsupported by facts or proofs of any kind. There is no doubt much done in the way of such adulterations; but the cause of honest dealing will never be advanced by reckless charges of misdoings on the part of traders generally, nor will such a course secure or sustain for the Social Science Association a reputation for a truly scientific spirit and character.

Archæological Researches.

A renewed interest seems to be awakened in the East for prosecuting excavations in various parts for archæological treasures. Favored by the authorities at Constantinople, Dr. Schliemann is again busily excavating at Troy; and Mr. Rassam has permission to dig anywhere in Mesopotamia. With such a comprehensive grant, districts will be opened that have not hitherto been searched, and we shall hear of fresh discoveries at Nineveh, of explorations in the long hidden ancient city of Assur, and of endeavors to find the famous royal "record office," or "Babylonian Bank," as some assyriologists call it, in which were stored a large collection of mercantile tablets, representing the monetary transactions of a firm trading in the name of Egibi & Sons. It is curious, says the *Scientific American*, to have bills for corn and fruits, and woven goods, and invoices and vouchers from the days of Nabupalassar and Artaxerxes in the form of baked clay; but they are to be seen at the British Museum. The Arabs and Jews from whom they were obtained have kept the secret so well that the place in which they were discovered is not yet known to Europeans.

Kutha, now a group of great mounds, was the sacred university city of Babylonia, and had an extensive library, which is frequently referred to in mythological tablets discovered in other parts of the kingdom. It was from that storehouse of learning that the tablets giving an account of the creation were originally taken; and it is hoped that discoveries of other documents not less interesting will there be made.

In the mound of Nebhi-Yunus, search will be made for the palace of Sennacherib, in the expectation that some records of the latter years of that monarch may be found, "and possibly some accounts, however meager, of the second campaign against Hezekiah."

But besides all this, Mr. Rassam will make explorations in the country of that ancient people, often mentioned in scripture—the Hittites. The existence of mounds along the bank of the Euphrates has long been known; and under a certain group known as the mounds of Jerabolus, it is supposed that Carchemish, the Hittite capital, lies hidden. Inscriptions in an unknown character were found in that neighborhood a few years ago; and it is hoped that some key thereto may be met with in the course of the excavations now to be undertaken, and furnish to scholars the link wanting to connect Assyria with Western Asia. As the firman granted to Mr. Rassam extends over a number of years, we may trust that the interesting enterprise will be carried to a successful issue.

The Voltaic Pencil.

There is at the present time scarcely a single branch of industry to which electricity is not lending its aid. Art, however, has thus far received but little benefit from this source, if we expect the application of electricity to electro-metallurgy. An important discovery, however, has just been made in Paris, by M. Bellet, whose invention consists of a voltaic pencil, by the use of which designers and draughtsman may be enabled to dispense entirely with the aid of the engraver. The editors of *Electricite* state that they have examined beautiful proofs of lithographs and etchings obtained, without the use of the engraver, by the effect of a voltaic arc produced at the point of an ordinary lead pencil. Encouraged by this success the inventor has taken out patents in various countries, and a company has been formed to carry out the process, which will soon be placed before the public. At present there are being prepared models of a series of apparatus which will allow any artist, however ignorant of the mysteries of electricity, to reproduce immediately, and without the aid of any artisan, the most delicate and complicated drawings; and this, too, by a very simple process and at a very moderate price. By a slight modification of the system there may be produced: 1. Stencils analogous to those produced by the Edison pen; 2. lithographs; 3. etchings; 4. stereotypes for typographical work. The initiators of this discovery are confident that an entire revolution will take place in the process of illustrating papers by means of their electrography. Either copper or zinc plates may be used. A late number of *Nature* describes the *modus operandi* as follows: A thin sheet of paper is attached to the plate. One of the poles of a Rhumkorff machine is connected to the plate, and the other pole to the top of the pen. The electricity then runs through, making a spark which perforates the paper in whatever direction the artist directs the pen. As soon as the drawing is finished, the paper is rubbed over with greasy ink, laid on with an ordinary roller. The paper is removed, and the plate is dipped into the acid, which cuts away those portions not protected by the ink. The light of the spark is said to be sufficient for the artist, even when he works in a dark room; and the pen is stated to be as manageable as an ordinary pencil.

Evolution and Spontaneous Generation.

Rev. W. H. Dalinger, who is well-known through his combat against the theory of spontaneous generation, lately delivered a lecture in London on the relations between his theory and that of the evolutionists. According to the report in *Iron*, there were, he said, many admirers of the theory of evolution who held that unless spontaneous generation was admitted, the theory was incomplete. Just as in water there is the potentiality of forming crystalline patterns in snow and ice, so they hold that in organic matter generally, there is potentiality of forming protoplasm. No living structure contains any known element that is not met with in the inorganic world, and the only chemical difference known is the combination of the elements. But the lecturer urged that evolution and spontaneous generation were two distinct questions that need very accurate study apart. The developmental progression of all living forms from simple protoplasm, is a very different question from whether living protoplasm can be spontaneously evolved from the inorganic world. For himself, if facts were brought forward to support spontaneous generation, he should be bound, were they valid facts, to accept the theory. He had, however, devoted much labor, and the time of years to the rigid investigation of some of the facts that bear upon the question, and these he would describe. It had seemed to him, in studying what had been written, that there were two lines of work that needed following out very closely. One was a series of thermal experiments, to determine with exactness what is the "death point" of an organism, or a "germ." The other was to watch the life history of some forms of monads and see if they did reproduce. It was this second line he had taken up. The most carefully conducted experiments of the first groups have led to the conclusion that if all germs are excluded from septic liquids no life appears, while his experiments had conclusively shown that monads do reproduce from parental products, and the life history of successive generations had been watched. The natural inference seems to be that monads originate only from previously existing monads, and if this is true of them, it is not improbable that observations conducted with equal care will show the same with regard to bacteria.

Mining Share Market.

The past week has been more exciting and active than any for eome time heretofore. The expected, upward tendeucy noted in our last issue, has been partially realized ; a eharp advance all along the line of the Cometocks having been experienced.

The amicable eettlement between the Comstock companiee and the Sutro Tunnel company, inaugurated this move for the better, and though no important ore bodies have been struck, the new lease of life, which this arrangement gives to the minee, the utility of the tunnel as a meane of drainage and better ventilation, and the certainty that in conjunction with it, new deep exploratione can be made in entirely virgin ground, eufficed to croate the strong upward impetus above noticed.

Even the upward movement in Yellow Jacket last week gave way to the interest elsewhere awakened along the Comstock. The principal movement on the north wae in Ophir and Mexican. Among the water stocke, Savage and Hale & Norcroes were the center of interest. Later, the leading etocks of Bodie and other outside districts became active, showing that more intereet is being taken in them as the spring advances. The latter part of the week ehowed less confidence and pricee were lower. Outsiders did not appear to appreciate the services rendered them hy manipulators in advancing "securities" to a higher standard, refusing to be accomodated even at previous prices. At the cloee of the week, pricee eomewhat recovered, and after a eteady etand, are again somewhat on the increase. No eharp rally is looked for, but more confidence is expressed in the general gradual riee, than would have been in case of a eudden spurt. In passing its February dividend, California has caueed eome dieappointment, it having been generally supposed that the now reduced rates could have been kept up eomewhat longer. Thie extinguiehee the last of the dividend-paying mines on the Cometock—takee away its "neet-egg," as it were. Meantime the Bodie, Eureka and other dividend-paying mines continue to dieburee their ueual amount of net earnings, and the productive minee everywhere to ehip their nsual complement of hullion, indicating an active and healthful condition of thie indu8try.

Throughoat the California mines, more especially in the bydraulic washiugs, great activity ie noticeable eince the advent of the recent heavy rains, whereby the reservoire bave been filled and the ditches eupplied to overflowing. The year now promisee to be a moderately good one witb every class of placer mines.

Bullion Shipments.

Since our last iseue, we have noticed the following bullion sbipments:

Highbridge, Feb. 7th, $10,027.35; California, Feb. 5th, $129,817.88; Bodie, Feb. 7th, $9,400; Hilleide, Feb. 5th, $5,370; Hillside, Feh. 9th, $5,200; Standard, Feb. 6th, $19,917.38; Northern Belle, Feb. 6th, $3,972.35; Alexander, Feb. 11th, $3,693.64; Tybo Con., Feb. 7th, $4,407.60; Leopard, Feb. 9th, $6,800; Independence; Feb. 10th, $4,000; Grand Prize, Feb. 10th, $12,500; Hilleide, Feb. 11th, $5,150; Indian Queen, Feb. 3d, $3,780.45; Northern Belle, Feb. 8th, $6,076.47.

METEOROLOGY.—Our knowledge concerning rainfall at different pointe on the Pacific coast is bcing constantly added to, and the etudy is generally associated with some intereeting condition of phyeical geography, or physical ecience, having a general and a wider bearing. Investigatione of thie sort are certainly practical enough ; though there is often at first glance, as in other departments of science, little hut abetract ecience to be seen on the eurface. Mr. Purnell concludes his eeries of articlee ou "Coemic Meteorology" in this iesue. The original obeervations of Dr. Blake, Prof. Le Conte and eeveral others, beforo the Academy of Sciencee, and ite eections, are to the point.

THE vote of Texas hae increased 50,000 in two yeare, wbich indicatee an increase of population in that time of hetween 300,000 and 400,000.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

MINING NOTES.—*Ledger*, Feb. 8: In the 230 and 270 levels of the Bunker miue the rock continuee as good ae ever. A steam pump has been put into the 270 level to throw the water up to the 70-foot drain tunucl. Another body of ore has been fouud in the 350 level, which it ie expected will turn out well. In the bottom level, 450 fect, the ledge bes been fouud eix feet in thickness and gradually getting larger. The mill is kept running all the time and pays woll. The Con. Amador made a mouthly cleau-up Suuday. Only one-half the milling capacity, or 20 stamps, was kept in operation. The yield was in tbe neighborhood of $10,000—a great shrinkage from the output of gold in its prietine days. The old worke are closed, with little prospect of their ever becoming the eccne of activity again. It doce not follow, however, that the miue is exhaueted. The mill is kept runniug to its full capacity on rock from the Wolverine tunnel and Badger shaft. At the Talisman mine, near Amador City, thinge are looking more hopeful than for many monthe past. In drifting north, towards the Keystoue, a body of quartz of fair quality has been etruck. The mill hae been operating on this rock for a couple of weeke. Water was turned into the More diteb Tuesday, and the new 10-stamp mill was etarted Thureday. All the works conuected with thie mine are of the most eubstantial character.

CALAVERAS.

UPPER COUNTRY MINING JOTS.—*Chronicle*, Feb. 8: The work of sinking the shaft in the Champion mine at West Point is progressing rapidly. It is now down 490 feet—the deepest ehaft in the county east of the Gwin mine. The mille in connection with the mine are in constant operation, the ore cruehed being first grade. The ehaft in the San Pedro, at Mosquito, is down 100 feet and deepening as fast as the bottom can be knocked out of it.

GWIN MINE.—The volume of water encountered iu the Gwiu mine continues eo large that it has heen found necessary to put in a larger pump from the 1500 level up to the first etation above. The work is now heing done, operations at the mine not being interfered with in consequence, however. All the hatteries are buey and will be kept so. Rock hae lately been etruck in the 1500 level, the ledge ehowing from eix to eight feet in width and the ore being of fair quality.

EL DORADO.

THE MINES.—*Republican*, Feb. 6: The El Dorado canal is frozen, keeping in check the claims dependent on it for water, the Park canal company sending down eufficient water to supply the demand aside from the Tenneseee claim. The Utah mine at Newtown ie also supplied from the latter canal, and the mill hae been running about two weeks. Ou the North-eide the Gold Depoeit was etarted up last Monday, the new concentratore having been put in place.

MINING ABOUT KELSEY.—*Mountain Democrat*, Feb. 8: We etill receive bighly encouraging reporte from tbe Gold Depoeit mine. The grading for tbe new concentrator bas been completed, and the work of putting the machinery together has commenced. The mill was started up for a test last Monday. Ore is being taken from the lower level, whicb carriee a large percentage of eulpburete of the fineet cbaracter. In that level the ore body remains firm and givee promiee of cheering reeulte, botb ae to quantity and quality. Work ie being proeecuted on the Esperanza mine, whicb is situated about one mile nortb of Johntown and within the great gold-bearing helt of that eection. The ore hody in the Esperanza is from two and a half to four feet in widtb, and proepecte well. A tunnel ie being run to tap it at a depth of about 100 feet. The Manefield hae been relocated under the suggeetive title of tbe "Cinche" mine.

INYO.

NEW FINDS.—*Independent*, Jan. 25: Fine gold quartz discoveriee have heen made near the foot of the lake, and there ie some excitement in relation to the matter. Quite a number of persons from Cerro Gordo and the hille around, have rushed off to some re-diecovered minee of Saline valley, eome 25 miles from Cerro Gordo. A new dietrict is being organized there called Mineral King.

THE ECLIPSE.—The Eclipse mill is running 15 etampe on gold ore when tbe weatber permits. Superintendent Eudey ie fitting up a five-stamp battery to run on silver ore, and a new amalgamating pan and a separate reeervoir for tailings.

MONO.

WEEKLY MINING REVIEW.—Bodie *Standard*, Feb. 8 : The work of developing our mines ie being advanced with gratifying rapidity, and each week's report improves the record upon which we ehall demand the attention of the world to this district the coming epring. Already, upon the strengtb of the mild weather which we have enjoyed thue far during the winter, quite an immigration of etrangere has commenced to eet in, anxious to he on hand in good eeaeon to participate in the lively times whicb everybody believes to he in the near future. During the past week the Standard, Bodie and Bulwer mines have been visited by partics of exteuded experience in miues, who express what would seem almoet exaggerated confidence in the vastness of the wealth as yet uuextracted from their deptbs. The probability of finding the Standard veins continuing in the Tioga at the north are eo great as to render it almost a certainty. Tbe prospects of opening out a vein in the Blackhawk, uow that a shaft is beiug eunk on the eouth end of that company, are first-class. The "lightning drift," 300 level of the Dudley miue, has not yet cut the Dudley ledge, but it muet reach it in a few days. We have heard pretty well authenticated rumors of a strike of some importance iu the Maybelle mine, eaid to be of base ore, whicb assays $100 per ton in silver. The Red Cloud is crosecutting west on its 400 level, and great thinge are anticipated of the Packard and Morton vein, which will be cut 150 feet below the point of discovery on the 250 level. The Noonday is looking very nicely, and the Richer is said to be taking out eome very rich ore.

ABOUT BENTON.—Inyo *Independent*, Feb. 1 : The mines around Beuton give more promises than pay. The Neal mine ie developing, aleo, the Sultan Hill. The Indian district contains fine proepects. The croppings there aeeaying from $30 to $65. Capital ie all thie country wants to make it a flouriehing section. The Clover minee are extensive and rich ; wood and water being handy, they can be cheaply worked. The Indian Queen ie giving great eatisfaction. A new company will etart up the old Comanche works. Many other claime present goed proepects.

NEVADA.

WATT GRAVEL MINE.—Grase Valley *Union*, Feb. 9: The main east drift is in 1225 feet; the lava has been passed and gravel found on the bedrock again; the bedrock is of a eoft blue elate. The north prospect drift hae been run 60 feet, the bedrock is elate. There is no change in the gravel and all work below the main drift has been etopped.

PITTSBURG.—Of thie mine, situated in the Nevada dietrict, the Superintendent's letter of the 1st inst. saye: The lode in the 600-foot drifte preeente well, it being well defined, carrying rich eulphurets. The etopee at 700-foot also preeent favorably, yielding large quantitice of good ore. The 800-foot etopes are being worked and yielding well. The lode at the 800-foot ie large and producing large quantities of ore. The mill is runniug well and doing good work.

IDAHO.—*Foothill Tidings*: On accoant of the loes of time by reaeon of ice in the ditch, the bullion yield last montb was only $39,500, but the usual monthly dividend of $7.50 per ehare, amounting to $23,250, was declared on Monday, payable immediately. This makee the 114th regular dividend paid by the compauy, amounting in all to $2,600,750, out of a total yield of the mine of $5,302,204.

ITEMS.—*Transcript*, Feb. 8: The Manzanita gravel mine near this city continues to be worked a part of the time, altbough the supply of water is light. There ie at preeent running in the main ditch of the South Yuba Canal Company about 3,000 inchee of water. There has heen a slight increase in the bead during the past few days, owing to the warm weather thawing out the emall etreams that lead into Soutb Yuba river and Deer creek.

PLACER.

VARIOUS CAMPS.—*Herald*, Feb. 8: Messrs. Lerman and Stuart, wbo have been engaged for eome time past in ruuning an incline in their drift claim, near Grizzly Flat, have struck a fine proepect, whicb they think ie eufficient inducement for them to run a tunnel of 700 feet on a grade eufficient to work their ground. August Hazelroth has aleo struck a good prospect in his drift claim adjoining the Rough & Ready. This will assure that company in prosecuting work in their claim with vigor and eatiefaction. But little water in the ditchee at preeent, and bueineee ratber dull. On Saturday laet tbe Orion Co., at Dutch Flat, diecharged a blast in their claim of 175 kegs of powder. The result was an admirable euccess.

PLUMAS.

GIBSONVILLE. — Plumas *National*, Feb. 1: The Bootjack mine ie turning out good pay, and a uugget weighing $81, was picked up in their dump a few daye ago. The Michigan ie showing good pay dirt, and Mr. Lowell thinke he has got the old lead ae good as ever. During the rain the company waehed np about a third of the dump-pile, dirt that wae not expected to pay but little, and they were agreeably eurprised by a clean-up of $1,300. The North American company is running two tunnele, and have good prospects. The mines in the Gibsonville neighborhood eeem to be holding their own and the epring will probably be a lively one.

SAN LUIS OBISPO.

LA PANZA DISTRICT.—*South Coast*, Feb. 5: On our arrival at La Panza dietrict we fouud eome 200 men actively employed, four-fifths of whom are native Californians—eome men digging, eome men packiug pay dirt to water, some rocking, eome panning, many walking over the country proepecting; all eanguine, all concurring in the wish for more rain. The main encampment ie in La Panza canyon, in which, and ite tributaries, ravinee and gulchee, is done all the present mining; prospects of fine gold are found nearly everywhere in the water courees; coarse gold is found in the ravinee and gulcbes. The great ecarcity of water at preeent in thie locality, and the lack of skilled lahor, is the cauee of the placere not yielding larger amounts to tbe operators. Evidencee are that "pockets," or rich deposits of gold, exist in the lower hills and flats which wash into the ravinee and gulches which are tribntary to the La Panza. The find in the preeent workings is indicative of what ought to exist in other parts of the dietrict which is more favored, having a large area of water-shed and an immenee depoeit of cement gravel. The belt of cement gravel has a length of six milee (the dietance explored and proepected by me) and a width of two miles. The topography of the country to the south and east on the line of the cement gravel showe it to be much broken. Tbe belt laye in a deep basin or channel; tbe cement gravel has the color and character of the gravel belt of Forest Hill and Yankee Jim, in Placer Co., of You Bet and Little York, in Nevada Co., of Moute Christo, in Sierra Co., and varioue hydraulic banks in Yuba Co., although the water shed ie larger in area; there never ie water enough to work by the hydraulic procese.

SHASTA.

COPPER CITY MINING ITEMS.—Reading *Independent*, Feb. 8: The continued fine weather for the past week has rendered it favorable for mining companice to pureue their workinge without interruption, and well have they improved the opportunity. The Extra company have their tramway completed and are now carrying from Bully hill to the company'e mill about 40 tons of ore per day, which is being reduced at eaid mill with ite ueual good reeults. This company have just completed their new emelting furnace and will make a teet of ite workinge to-day, and as there are many thoueand tons of good copper ore in this dietrict, which will pay well if succesefully worked by thie procees. We are all waiting anxiously the reeult of the emeltere to-day. Ae there are two other companies who have endlese quantitiee of good emelting ore, it will make times very lively in thie place the coming epriug, ee there will doubtlese be a number of these furnaces erected. The Potter mine ehows better ae they sink deeper, opening up a wonderful body of rich ore. The tunnels in the Northern Light and Winthrop minee are being puehed forward as faet as poseible.

SIERRA.

HOWLAND FLAT. — Dowuieville *Messenger*, Feb. 8 : When "The Empire" stopped work, about 40 white men were eent adrift. Some have gone to Foreet City to work in the celebrated "Bald Mountain," some to Gibeonville, and neighboring towne. We all hope the Bonanza company will eoon be in with their tunnel, for it will then be in their power to call the miners back and reetore the lively times. The Empire paid well every month. The Bonanza will probably do the eame. If it paye well, how much better it would be for the people of the town, and aleo the Bonanza company, if the latter would employ white men only. That *would* "make things lively." Not ouly that; look at the example eet for othor companiee. The Buttes Quartz Co. ie working about 100 men but the preeent etorm will prohably enable them to put on a full force.

TUOLUMNE.

VALUABLE MINE.—*Independent*, Feb. 8: The Basin Slope mine, located ahout eight milee weet of Cherokee in thie county, ehowe immeuse bodies of ricb galena sulphureted ore, assaying from $200 to $350 per ton. The mine is the property of Meeere. Lewis Broe.

THE MELONES MINE.—The immenee reduction works at Melonee mine, near Robineon's Ferry, are nearly if not quite complete, and many will await with considerable intereet the reeult of the venture. The machinery is, eo to epeak, incomprebeneibly grand and intricate to the eye of a tyro in mechanism ; in fact, the daze of helting, ehafting and pulleys ie like unto a drunken man'e dream. But if it worke up to echedule it will be a grand thing. A great portion of the machinery was brought from Boston. Ae the procese has proved eucceeeful in reducing the tellurium oree of Arizona, it is confidently expected to operate ae well upon the rich but rehellioue matter of the Careon Hill mines. It ie a hig thing, and bae coet a mint of money.

YOLO.

CALIFORNIA QUICKSILVER MINE.—Yolo *Mail*, Feb. 6 : R. G. Hart aesietant Superiutendent of the California Quicksilver mine, made ue a call yeeterday. He reports the mine doing much better than for a year past, but the company only running a forec of 30 hands ae minere. They are running two furnacee conetantly—one for the reduction of fiue ore, and one for coaree ore. With quicksilver at 39 cents per pound, the mines yielded sufficient during the month of January to produce $3,000 over and above all expenses, including the per cent. paid for sale of quicksilver. This is a pretty good ehowing for eo emall a force of workmen.

NEVADA.

WASHOE DISTRICT.

SIERRA NEVADA.—Gold Hill *News*, Feb. 12: To-day the southeast drift on the 1700 level will reach a point directly under the North Con. Virginia ehaft. As soon as the neceseary arrangements are completed, an upraise to connect with the bottom of the shaft will he commenced. When this connection is completed, the ventilation of the mine will be the hest possihle down to the 1700 level. Work is heing puehed vigoronsly at all points.

CALIFORNIA.—The north drift, on the 2150 level, running to connect with the eouth drift on the 2000 level of the Ophir, is now in 120 feet, the face in very hard hlasting gronnd. In the drift south from the Ophir, on the 2000

Continued on page 108.

What the English think of our State Pride.

A correspondent of the London *Times* has been in this country, and touches off our State pride in this manner.

The rivalry which prevails among all the States of the American Union is especially keen and conepicuoue in Minnesota. Each State, from rugged Maine to sunny Florida, and from imperial New York to golden California, conceiders that no other one rivals or excels it. The citizens of each speak as if they had been placed by a kind Providence on the most favored spot of the whole earth, and they regard the stranger who doubts whether their good fortune be wholly exceptional as a person who ie utterly ignorant and inexcusably prejudiced. Indeed, a new comer will ingratiate himself the moet easily with the citizens of a particular State if he can look upon all others, for the time being, through their spectaclee. His wisest course will be to copy the example of the Frenchman ridiculed and stigmatized by the late Gen. Sir Charles Napier. That renowned soldier and eccentric man entertained the conviction that all Frenchmen are hypocrites, and he illuetrated this harsh and ungeneroue opinion by saying, "If a Frenchman were to go to hell, he would put on an overcoat, compliment the Devil on the fineness of the climate, and add that, if anything, it was rather chilly." I once eaid eomething to a Penneylvanian, alike laudatory and merited, with regard to hie State. He accepted the compliment as a matter of couree,- and replied, "That'eso; Pennsylvnia is best in everything." Traveling in Colorado shortly after the late total eclipse of the sun, I remarked, in the preeence of eeveral citizens, it was fortunate that the weather had been eo favorable there for the purpoee of observation. One of them told me, in reply, "Sir, Colorado can beat the world in eclipses, as in everything elee."

These instances might be multiplied. They all exhibit that pride in one's State, which is as notable a characteristic of a United States citizen as pride in hie country. When Capt. Basil Hall traveled in North America he bitterly complained of the pertinacity with which everyone demanded hie opinion about it, and of the extreme annoyance which was manifested if the reply was not unreservedly complimentary. It is far less common now than in bygone days for a etranger to be questioned concerning his views of the Republic as a whole, and to be expected to draw a flattering comparison between it and what the ignorant call the effete monarchies of Europe. It ie far more probable that he will be aeked by the citizene of one State what he thinks of another, and then, unless he dieplay a little of that French politeness which Sir Charlee Napier detested, be will give ae much offence as Capt. Basil Hall gave when he denied that the United States was the only land worth living in.

Cosmic Meteorology.—No. 4.

[Written for the PRESS by SAMUEL PURNELL.]

As to the cause of eun-spote a curious theory was broached many years ago, and recently it has been pretty well confirmed, to the effect that they are caused by the orbital approach and recession of the planets. Just how they cause eun-spots when in perihelion, producing a maximum when conjoined, cannot be said, but the coincidence in the time of their joint peribelia and the maximum of spots is undoubted. Prof. Loomis has advocated the theory of a long cycle of 56 yeare, as related to the eucceseive conjunctione of Saturn and Jupiter. This is not as distinctly marked ae the 11-yeare cycle. Prof. Wolf has aleo discovered several minor periods of solar activity. By projecting his reeults in a continuous curve, he found in it a series of small undulations succeeding each other at an average interval of 7.65 months, or 233 daye. This is nearly the mean interval between the successive conjunctions of Venus and Jupiter, which is 236.992 days. The close agreement of theee periods leaves little room to doubt that the latter is the true period. Prof. Wolf hae also detected a period of variation corresponding to the sun's time of rotation, with respect to the earth, or ahout 27 days. It has also been found that the eun-spot cycle is nearly equal to 18 periods of Venus, to 35 synodal periode of Mercury, to one period of Jupiter, aud to several other planetary conjunctions.

The Kew Professors, Messrs. Stewart, de la Rue, and Loewy have recently examined this subject anew, and have traced out the relation between certain poeitions of the planets and the amonut of eun-spote during a cycle, ehowing that the principal planets, Mercury, Venus, Earth, and Jupiter, in their approach and withdrawal from the suu, do have much, if not a controlling, influence upon the spote. It will be seen that the astronomical theory as to the cause of the spots ie very complicated, and demands great labor to establish or disprove it. It has been thought that each planet in coming to and going from perihelion, more especially about the time of the equinoxes, produces a violent action upon the eun, and hae a eympathetic action produced within itself; and that when eeveral planete happen to be coming to or going from perhelion at the same time, aud are in or nearly in the same line with the sun, being nearly in the same plane, the combined action producee a maximum of sun-epots. According to Prof. Stewart, the planetary periods at times of maximum sun-epote are found to be greater than the average value.

Ae it is my intention to publish further investigations in future into the queetion of the relation of the movements of the planets to the spote, thie branch of the eubject ie herewith ahruptly cloeed; merely remarking that thie eolar, planetary, and phenomenal connection ie etartling, in that it eeeme to indicate a revival of

Astrology

On purely scientific grounds, for eince great phyeical terrestrial motione can be affected by the position of the planets, it ie natural to aek why may not human life be aleo affected, favorahly or unfavorably, as it can hardly be a matter of indifference to mankind what ie tbe potency of the governing forcee of the earth.

Having already etated euch general matters concerning eun-epots as are of common interest, an effort will now be made to eee how closely their periodicity may coincide with any periodicity in the

California Rainfall.

In thie a difficulty of great moment is immediately encountered, in the fact that not sufficient time has elapsed whereby true cycle averages can he obtained; neither have there been enough oontinuous obeervers, nor the rainfall of enough statione noted whereby an average preeipitation throughout the State can be safely deduced. In view of these almost fatal difficulties it can hardly be expected that the eurprising yearly variations of rainfall here can be brought within any rule, yet with all these dieadvantagee it will be eeen later on, that in many cases there is a curious agreement of the rainfall with the eun-epot curve, and in other caeee an equally curious disagreement; and I must confese, at present, I know not of any process by which to harmonize the results.

The meaeured rainfall of four California stations from 1849-50 to 1877-78; that is, from the summer of one year to the eummer of another (there being but an ineignificant rainfall during the summer), was as follows:

YEAR.	San Francisco.	Stockton.	Sacramento.	San Diego.	Mean.
1848-49	15.99	7.99	11.00	7.99	19.99
1849-50	33.10	39.00	36.99	6.27	27.84
1850-51	7.40	4.71	4.71	7.25	6.02
1851-52	18.44	17.93	17.98	19.95	16.34
1852-53	35.26	27.49	36.37	8.61	20.91
1853-54	23.87	21.94	20.07	11.33	19.98
1854-55	23.68	11.68	18.62	12.99	16.73
1855-56	21.66	8.37	13.77	19.79	13.62
1856-57	19.81	11.33	19.44	7.66	12.32
1857-58	21.88	18.99	15.99	8.68	16.14
1858-59	22.22	19.94	16.94	12.19	16.61
1859-60	31.22	22.72	22.63	6.85	29.85
1869-61	19.72	15.55	16.09	5.92	14.24
1861-62	49.27	35.55	35.55	11.39	32.92
1802-63	13.62	11.58	11.58	5.92	19.67
1803-64	19.98	7.86	7.87	7.26	8.27
1864-65	24.73	22.51	22.51	8.27	19.59
1865-66	22.93	17.92	17.92	13.51	18.97
1866-97	34.92	25.31	25.31	18.29	25.93
1867-68	38.84	29.71	32.77	13.42	26.44
1868-69	21.35	16.35	16.64	11.91	16.56
1869-79	19.31	7.63	13.57	9.49	11.72
1870-71	14.19	9.73	8.47	7.67	9.24
1871-72	34.71	20.80	22.40	6.22	21.93
1872-73	18.02	13.39	13.50	8.20	13.25
1873-74	23.98	15.20	23.99	15.10	19.32
1874-75	18.49	11.14	17.89	6.19	13.36
1875-76	29.01	18.33	25.09	9.93	19.89
1876-77	19.99	7.93	9.25	3.63	7.43
1877-78	32.15	18.00	22.55	19.19	22.29
1878-79					

It will be oheerved that the rainfall of 1848-49 is aleo given, as approximated from descriptione given me by old reeidente of the State, of the mountain etreams ae compared with their volume in years of known rainfall, and it is fairly accurate. The recorde for tbose early yeare for Stockton, which are the eame as for Sacramento, have probably been last and entered as of the same amount as for Sacramento.

A Curve

Will be traced from theee etation resulte and from the column of means and compared with the eun-spot curve.

The mean relative number of sun-epots for the yeare corresponding to the rainfall teble, as given by Dr. Wolf, is as followe:

Year.	Number.	Year.	Number.
1848	124.9	1864	45.2
1849	95.4	1865	31.4
1850	60.8	1866	14.7
1851	63.2	1867	8.8
1852	52.7	1868	36.8
1853	38.5	1869	78.6
1854	21.9	1870	131.8
1855	7.7	1871	113.8
1856	5.1	1372	99.7
1857	22.9	1873	67.7
1858	59.2	1874	43.1
1859	99.3	1875	18.9
1860	94.8	1876	11.3
1861	77.7	1877	7.9
1802	61.9	1878	
1803	45.4		

The probability that the

Present Year, (1878),

Is the extreme minimum sun-spot year of the current cycle will be made clear by the following exhibit of the epote for each month down to the cloee of October.

1878. Month.	Relative number of sun-spots.
January	.79
February	2.32
March	2.67
April	.35
May	2.35
June	1.66
July	——
August	——
September	.36
October	.74

No spots were observed duriug July and August. It may, therefore, he safely aesumed that August, 1878, was the close of the prcsent eolar cycle. The mean relative number of epots for the 10 months stated above ie but 1.11, and if a like proportion is continued to the end of the year, then it will prove to have been the extremest minimum during this century, with the possible exception of 1811.

The oscillations of the

Sacramento River,

At Sacramento, were recorded by Dr. T. M. Logan for many years, and he published a chart of their hight above low-water mark for the 13 years from 1849-50 to 1861-62, inclusive. Dr. Logan died a few years ago, and all tracee of his records after 1862 have disappeared, and no figures can be obtained till 1875, from which time on the Central Pacific Railroad Company have taken daily oheervations.

Mean Annual Hight of Sacramento River at Sacramento.

1849-59	9.5 feet	1857-58	5.7 "
1850-51	2.4 "	1858-59	9.6 "
1851-52	7.6 "	1859-60	7.4 "
1852-53	19.5 "	1869-91	8.7 "
1853-54	6.5 "	1861-62	13.9 "
1854-55	8.0 "	1875-76	9.6 "
1855-56	4.0 "	1876-77	4.5 "
1856-57	5.6 "	1877-88	11.5 "

The measuremeuts are from September to September; as during the winter of 1877 the river burst its banke and a large amount of water did not flow by the gauge, which recorded but 10 feet and 8 inchee, tbe mean hight of the water for that year has been approximated ae 11.5 feet.

Having now the rainfall of four etations for 30 yeare; the oscillatione of the Sacramento river for 16 years, and the mean relative number of eun-spote for the correeponding time, it ie poeeible to

Project the Results

Of each into curvee and to compare them eide by side. A diagram of euch curves ie ae followe:

With the tablee and diagram before him each reader can now form hie own conclusione, yet a few remarks upon the singular agreemente, diecrepancies and variatione to be eeen may not be improper.

It will be noticed that the sun-spot maxima have occurred in 1848, 1860, and 1870, in each year of which the rainfall has been much below the average; this, however, has been iu a degree harmonized by the rainfall of the next succeeding years, for it will he noticed that in 1849, 1861 and 1871, (the years next after the sun-spot maxima) the rainfall hae been greatly ahove the average. Thie shows that during two complete cycles the two maxima under consideration have nearly coincided, the rainfall maxima lagging a year behind the eun-spot maxima; and this has been proved to be the caee elsewhere with rainfall and otber phenomena. Why the rainfall of the year of maximum sun-epote should be iteelf a minimum, in the face of the powerful solar disturbance at such time, cannot be etated, but the fact is sufficient to strongly indicate the existence of a douhle oecillation of rainfall within the 11-years cycle. The yeare of minimum eun-spots are 1856, 1867 and 1878 (probably), of these the raintall of 1856 was below the average, of 1867 much above the average, while that of 1878 ie too eoon to etate; although at preeent writing there are appearing strong grounds for anticipating a minimum rainfall. Provided 1878 proves to be one of minimum rainfall, then during two complete minimum cycles we ehall have had two years of minimum rainfall and one of maximum; this last, however, is quite eufficient to destroy the uniformity of proceedings and prevente the harmonization of the two epochs. In the yeare before the date of minimum sun-epots, corresponding inversely with the results during the maximum yeare, it will be noticed that the rainfall has been much above the average, with the single exception of 1856; this again coutrihutes its quota of evidence toward the probability of a double rainfall oecillation. When the figures for two more cycles ehall have been obtained, thie double oecillation may more clearly appear.

The attention of the reader is called to the pleasing

Relativity

Of the sun-spot and Sacramento River oecillation curvee from 1852 to 1861. The river being the product of the raiufall upon the Sierra Nevada mountains, the equivalent of many millions of rain gauges, it seems reasonable to assume that were a complete and accurate record of its oscillations obtainable its curve would ehow a eurprising conformity with the sun-epot curve, directly and inversely.

By arranging the rainfall of a

Series of Years,

From 1850 to 1876, after the manner of Dr. Hunter, so ae to correspond with the sun-epot numbers for the eame years, ae divided into minimum, intermediate aud maximum groupe,

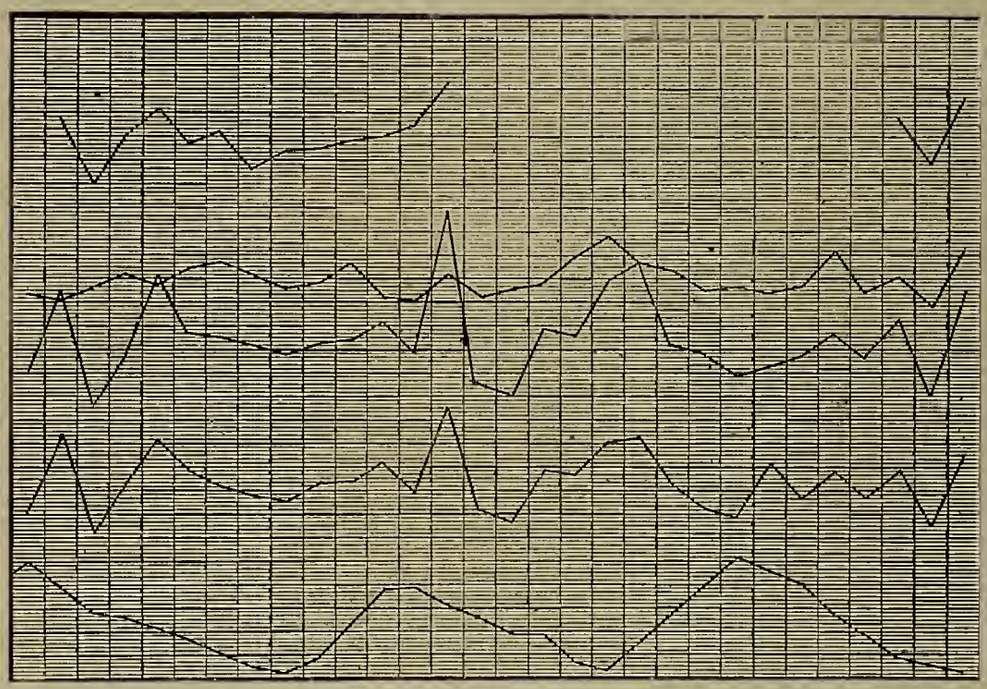

DIAGRAM SHOWING THE MEAN RELATIVE NUMBER OF SUN-SPOTS AND MEAN RAINFALL FOR THIRTY YEARS

the following result will be obtained.

Minimum years.	Mean rainfall.	Intermediate years.	Mean rainfall.	Maximum years.	Mean Rainfall.
1876	7.48	1867	20.44	1869	11.72
1885	18 97	1856	12.32	1858	16.61
1854	16.73	1868	16.56	1879	9.24
1876	25 93	1857	16.14	1850	20.85
1855	13.62	1873	19.32	1871	21.93
1875	19.89	1862	19 67	1869	14.24
1864	19.59	1861	16.34	1849	27.84
1853	19.98	1874	13.36	1872	13.25
.....	.....	1883	8.27	1861	32.92
.....	.....	1852	20.91	1859	6.92
Mean.	17.53	Mean.	16.03	Mean.	17.37

By this table it will be seen that the total rainfall in Hunter's minimum and maximum-year groups is very nearly the same, and that only the intermediate group shows a less than the average amount; which is further evidence of a

Double Oscillation

Of rainfall, and of the fact that the relative quantity of rainfall is more constant than has generally been supposed.

The above facts and deductions are further evidenced from the following table of rainfall during the actual minimum, maximum and intermediate groups (the minimum group, including the year before and the year after the actual minimum sun-spot year; the maximum, similar; the intermediate, the balance of the years in the cycle).

Minimum groups.	Rainfall.	Intermediate groups.	Rainfall.	Maximum groups.	Rainfall.
1855	13.62	1858	16.61	1859	20.85
1856	12.32	1862	19.67	1860	14.24
1857	16.14	1863	8.27	1861	32.92
.....	.....	1864	19.59	.....	.....
.....	.....	1865	18.07	.....	.....
Mean.	14.92	Mean.	16.50	Mean.	22.67
1866	25.93	1872	13.25	1869	11.72
1867	26.44	1873	19.32	1879	9.24
1868	16.56	1874	13.36	1871	21.93
.....	.....	1875	19.89	.....	.....
.....	.....	1876	7.48	.....	.....
.....	.....	1877	22.29	.....	.....
Mean.	22.97	Mean.	15.91	Mean.	13.99
Mean of both Groups.	18.49	Mean of both Groups.	16.20	Mean of both Groups.	18.33

A Curious Result

Will be noticed in the above table, that during the first cycle, from 1855 to 1866, the rainfall was strictly and directly relative to the sun-spot numbers; that during the second cycle, from 1866 to 1877, the rainfall was inversely relative to the sun-spot numbers; and that the means of the two cycles again show the nearly equal amount of rainfall during the minimum and maximum sun-spot groups. This to me, at present, seems conclusive that there is, so far, upon the average, during a sun-spot period a double oscillation in the amount of rainfall in California.

Those who have leisure and inclination may profitably compare the two last preceding tables of rainfall with corresponding tables of sun-spots, noting the differences and agreements; also, strike an average of the rainfall in the two sun-spot cycles, and compare its curve with the average sun-spot curve for the same period.

It may be interesting to construct a table of the rainfall of California from 1849 to 1874, inclusive, after the ingenious system used by Dr. Meldrum in proving the

Periodicity of the Rainfall

Of Paris and Edinburg. The column headed "mean cycle" is a harmonic mean of the preceding column, found by taking the first term, twice the second, and the third term; adding together and dividing the sum by four; and so on for each term of the "mean cycle." The variation is simply the difference plus or minus of each term of the "mean cycle" from the average thereof. This table will also show the correspondence between the rainfall and the sun-spots, and the double oscillation of the former within the cycle of the latter. The minimum years are in the second line.

Year.	1849. 1891.	1862. 1874.	Means.	Mean Cycle.	Variat'n of Rainfall	Variation sun spots for same periods.	Year of 11 years' Cycle.
1	27.84	19.67	19.25	.....	.....	.....	.....
2	6.92	8.27	7.14	12.86	— 4.29	+ 7.2	1
3	16.34	19.50	17.92	16.36	— .79	— 2.7	2
4	26.91	18.97	22.49	21.35	+ 4.29	— 13.5	3
5	19.98	25.93	22.59	22.20	+ 5.11	— 27.2	4
6	16.73	26.44	21.58	20.18	+ 3.93	— 35.1	5
7	13.62	16.56	15.99	15.94	— 1.21	— 28.2	6

9	19.14	9.24	12.69	14.95	— 3.19	+ 16.9	8
10	16.91	21.93	18.82	16.84	— .31	+ 39.8	9
11	20.85	13.25	17.05	17.42	+ .27	+ 34.3	10
12	14.24	19.32	16.78	18.43	+ 1.28	+ 24.7	11
13	32.92	13.36	23.14	.....	.....	.....	.....
..	.....	.....	.....	.....	.....	.....	.....
..	.....	.....	.....	17.15	.....	.....	.....

Here I close the subject, for the present. The reader will not fail to be struck by the

Insufficiency of the Evidence

Yet produced to prove the truth of the theory, as especially regards California, and its want of certainty compared with the value of the problem to be solved. Surely few things could be of more value to Californians than to be possessed of an infallible rule whereby to prophecy the coming winter rainfalls. This will be attained in future, but it is plain the time is not yet arrived. That Science is upon the right track, in swift pursuit of the fleeing mystery, seems apparent; but before it can be won, and this secret of nature be revealed to man and applied to his use, many years must pass by, many more sun-spots be observed and their causes known, many more measurements of rainfall from many additional stations must be made, many more observations of correlative phenomena must be recorded and explained, many more weary days and years of working and waiting must be endured. But the reward will come at last, when the mystery is revealed.

[Concluded.]

Useful Information.

A New Mode of Locomotion.

The newspaper carrier who serves papers to the attendants in the permanent exhibition building in Philadelphia, goes his rounds at the rate of 12 miles an hour. He travels on machines not unlike roller skates, which are called podomotors, according to the inventor, Mr. J. H. Hobb, an architect on Walnut street, above Fifth. The day is not far distant, predicts the Philadelphia *Record*, when the whole city will be on wheels, when pedestrians will be skimming through the streets at the rate of 10 miles an hour, without more effort than is now put forth in perambulating half that distance.

The podomotor consists of four tough, light, wooden wheels, supplied with an outer rim of tough India-rubber. These wheels are secured to a frame the shape of the foot, which is strapped to the pedal extremities in the usual manner. Unlike roller skates, the wheels of these little vehicles are not under, but are placed on each side of the foot, thus giving the wearer a good standing, as well as a solid footing. The rear wheels are three inches in diameter, while those in front are but two and one-half inches. This gives the foot a slight incline, and when in motion has much to do in impelling the pedestrian forward. Extending from the toe, with a slight curl toward the ground, is a piece of casting termed the pusher, which is simply used in mounting an elevation or steep incline. From the center of the heel a small brass wheel extends backward, serving as a guide as well as a break. The whole scarcely turns the scale at a pound weight. In using them no more effort is required than in ordinary walking. The wearer steps with his regular stride, and is amazed to find himself skimming over the ground so rapidly with so little muscular effort. Mr. Hobbs explains the mystery of the rapid movement in this manner: A man whose stride is 32 inches will traverse 48 inches, or one-half further, with the podomotor. This is because the body is in constant motion. For instance, says he, the traveler starts, and while he raises one foot to step, he continues rapidly onward until that foot is set down and the other raised to make another step. This gives him more momentum, and away he goes over the two miles in the same time to accomplish a mile with the feet. No effort of the body is required for their use, as in skates. The traveler simply puts one foot before the other, and finds himself whizzed along at a lively rate.

Frozen Fodder.—A German chemist, Dr. Paagel, has been investigating the effect of frost on cabbages and other plants used as fodder for cattle, and the best method of utilizing frozen plants. The principal change effected by the frost he finds to be a formation of sugar from starch; and as sugar has a nutritive value corresponding to the quantity of starch from which it has been produced, he considers that no reduction in the nutritive value of the plants occurs through freezing. Care must be taken, however, about the delivery of the frozen plants. First, they should not be given in the low state of temperature they possess, and then they must not be allowed to lie long after thawing, else (probably from the formation of diastatic ferments) they pass into putrefaction, and so may easily do harm. They are probably best used when given as fodder immediately after thawing, or after preparation by steeping in hot water or steaming. A long time after thawing, frozen plants cannot be given as fodder without danger.

Preserving Wheat.—It is said that in Poland, where ventilation and drying are continued for some time, wheat has been kept sound and good for half a century. Its age never does it injury, and such wheat is said to yield handsomer and better flour than that obtained from grain more recently harvested. At Dantzic, the preparation for keeping wheat continues for a year or longer, and after this period it is often kept for seven years, perfectly sound, in large granaries, although Dantzic is surrounded by the sea. These facts show how easily wheat may be preserved if proper precautions are taken. But the most striking feature is that some of the wheat found in the Pyramids of Egypt, and perhaps more than 3,000 years old, was still good enough to grow when sown, and produced a crop perfectly identical with the present wheat, proving that the character of this plant has not changed during that time.

Water in Bread.—One hundred pounds of flour contain, of dry material, 84 pounds, and of natural water, 16 pounds, while 150 pounds of bread would contain, in addition to the 84 pounds of dry substance and the 16 pounds of natural water, 50 pounds of added water. Loaves of bread become lighter in weight by baking, because during the process a larger quantity of water is driven off, and yet the reason why bread, which contains fully 40% of water after baking, retains so much of this liquid, is because during the baking the starch is converted into gum, which holds water more strongly than starch does; and also because the gluten of flour, when once thoroughly wet, is very difficult to dry again, forming a tenacious coating round every hollow cell in the bread, retaining the gas and water. Again, the dry crust which forms round the bread in baking is nearly impervious to water, and prevents the moisture within from escaping.

Paraffine as a Lubricant.—A correspondent of the *Railroad Gazette* announces that the Erie railroad has reduced its oiling expenses from $5,000 to $1,000 a year by using paraffine on passenger car journals, and has reduced the number of hot journals from 535 to 332. It is now used during the winter months, without the addition of any other oil, but it is found that in summer it becomes so limpid that it is hard to keep it in the axle boxes. During the summer months it is therefore mixed with some other lubricant to give it more "body."

Coating Copper Plates with Iron.—Prof. Bottger recommends the following solution for coating copper plates with iron: Ten parts of ferrocyanide of potassium and 20 parts of tartrate of soda are dissolved in 220 parts of distilled water, adding a solution of three parts of sulphate of iron in fifty parts of water. Caustic soda solution is poured into the mixture until the Prussian blue formed is redissolved.

The oldest pieces of wrought iron which are known are probably the sickles found by Belzoni under the pedestal of the sphinx, in Karnac, near Thebes; the blades which Wyse found imbedded in the wall of the great pyramid; and the piece of a saw which Layard dug up at Nimrod. These remains are now owned by the British Museum.

Woods Heavier than Water.—The woods which are heavier than water are Dutch box, Indian cedar, ebony, lignumvitæ, mahogany, heart of oak, pomegranate, vine. Lignumvitæ is one-third heavier, pomegranate rather more. On the other hand, cork, having a specific gravity of .24 and poplar of .383, are the lightest woody products.

Good Health.

A National Department of Public Health.

Mr. Lamar's bill, now before Congress, "To establish a new Department of Public Health" at Washington, having been already read a second time and referred to a committee, the necessity is urgent for an immediate and thorough examination of the merits of the proposed measure, the importance of which cannot be overrated.

The aim of Mr. Lamar's bill is for the purpose of acquiring and diffusing useful information on subjects connected with the public health; to establish, direct and manage sanitary and quarantine systems and regulations throughout the States and Territories of the United States; to supervise the Marine Hospital service, and to organize and direct a corps of sanitary engineers competent to superintend all public works so far as their construction may affect the public health.

The chief executive officer of this Department will be styled the "*Director General of Health.*" It will be his province to perform all the duties and exercise all the powers now devolving upon the Supervising Surgeon-General of the Marine Hospital service, which office is abolished by the bill. He will make and enforce all quarantine and other regulations for the prevention of cholera, yellow fever, and other epidemic diseases. He will also have power to select sites and establish quarantine stations and erect buildings. It will also be his duty to prepare suitable tables at the taking of each census, to embody such facts relating to births, deaths and marriages, the prevalence of disease or other data which may serve as a basis for securing a complete system of vital statistics for the United States, and make an annual report of his Department to Congress.

The work of the Department will be carried out by whatever additional officers are required, including chief clerk, chemists, engineers, scientists, experts, etc. The Director will also have the power, under this bill, to employ at all times persons of proper scientific knowledge and skill, to make special investigations on subjects connected with the public health, awarding these compensation, as he deems reasonable and just.

In this connection it may be remarked that the American Public Health Association has recently prepared and presented a report in regard to the character of the action which Congress should take in this matter. This association advises that Congress should take no steps at this time to organize a permanent national department of health, believing such legislation would be hasty and unsatisfactory. They, however, expressly state that they are not opposed to a national quarantine system, but that it is impossible to organize such a system at the present time.

The Association, however, make the suggestion that Congress shall immediately provide for the proper organization of a "Provisional National Health Commission," the objects and duties of which shall be to report to Congress at its next session a plan for a permanent national public health organization, to be prepared after consultation with State Boards of Health, and withal possessing special knowledge and experience on the subject. They would also take charge of investigations into the causes and prevention of yellow fever and other epidemic diseases, and such administrative duties connected with the investigations, which, I presume, means the direction of preventive measures in regard to any outbreak of yellow fever, which may probably be looked for during the approaching summer.

The memorial is full of excellent suggestions in regard to the organization of the Commission, and, in this respect, forms a great contrast to the bill of Mr. Lamar, which is crude in form, and in effect creates an absolute dictatorship of health, with unlimited powers for good or evil.

Dieting for Health.

Dieting for health, says *Hall's Journal*, has sent many a one to the grave, and will send many more because it is done injudiciously or ignorantly. One man omits his dinner by a herculean effort, and thinking he has accomplished wonders, expects wonderful results, but by the time supper is ready he feels hungry as a dog, and eats like one, fast, furious and long. Next day he is worse, and "don't believe in dieting" for the remainder of his life.

Others set out to starve themselves into health, until the system is reduced so low that it has no power of resuscitation, and the man dies.

To diet wisely, does not imply a total abstinence from all food, but the taking of just enough, or of a quality adapted to the nature of the case. Loose bowels weaken very rapidly, total abstinence from all food increases the debility. In this case food should be taken, which, while it tends to arrest the disease, imparts nutriment and strength to the system. By resting on a bed, and eating boiled rice, after it has been parched like coffee, will cure three cases out of four of common diarrhœa in a day or two.

Others think that in order to diet effectively, it is all-important to do without meat, but allow themselves the widest liberty in all else. But in many cases, in dyspeptic conditions of the system particularly, the course ought to be reversed, because meat is converted into nutriment with the expenditure of less stomach power than vegetables, while a given amount of work does three times as much good, gives three times as much nutriment and strength as vegetable food.

Man's Age.

Few men die of old age. Almost all die of disappointment, passion, mental or bodily toil, or accident. The common expression, "choked with passion," has little exaggeration in it, for even though not suddenly fatal, strong passions shorten life. Strong-bodied men often die young; weak men often live longer than the strong, for the strong use their strength, and the weak have none to use. The latter take care of themselves, and the former do not. As it is with the body so it is with the mind and temper. The strong are apt to break, or, like a candle, to run; the weak to run out. The inferior animals that live temperate lives have generally their prescribed number of years. The horse lives 25; the ox 15 or 20; the dog 10 or 12; the rabbit 8; the guinea-pig 6 or 7 years. These numbers all bear a similar proportion to the time the animal takes to grow to its full size. But man, of all the animals, is one that seldom lives this average. He ought to live 100 years, according to physical law, for five times 20 is 100; but instead of that he scarcely reaches on an average four times his growing period; the cat 6 times, and the rabbit even 8 times the standard of measurement. The reason is obvious, man is not only the most irregular and intemperate, but the most laborious and hard-worked of all animals. He is also the most irritable, and there is reason to believe, though we cannot tell what an animal secretly feels, that more than any other animal, man cherishes wrath to keep it warm, and consumes himself with the fire of his own secret reflections.

Chloral as a Counter-Irritant.—Among the many uses to which chloral has been put, we have not met before with the following from the *Bulletin Therapeutique:* Made into a mass with gum tragacanth, spread on paper and applied to the skin, it will produce a blister without pain. Applied as a powder, on cotton, it causes a painful burning sensation. By the former method a portion is absorbed, and the patient falls asleep. Its action is not so uniform as cantharides, but as a mild vesicant, or an agreeable revulsive, the author quoted would commend such "chloral paper" to physicians, the more so, as it will keep for months without losing its activity, if well prepared.

The Week.

All this week we have been visited by a welcome, good old-fashioned rain, which is worth millions to us, for it hrings ue strong hopes of a plentiful crop. News from the hydraulic mining sections represents that they had heen nearly all limited in operations through lack of water, and to them this storm will be a godsend. But little of interest has occurred in mining circles, except that the Bodie miners have struck for higher wages and forced the mills to shut down. There is some excitement in Oregon over new finds in gravel washings, and a false one in Gilroy over a fictitious silver ledge.

Political parties are waking up and striking the preliminary notes to the coming campaign. Conéiderable discussion is heard coucerning the University land hill, now before Congress, and the facilities it affords for "grabbing."

From Africa comes the tidings that the Zulus have utterly annihilated a British army, which affords a text for Gladstone from which to preach Beaconsfisld a sermon.

An indignant wail comss up from Arizona over the assignment of certain of her lands by Congress, to the Indians for a reservation.

Serious charges of corruption have been laid before the Board of Supervisors against the Board of Education and others implicated in the late school scandal.

Weather Districts.—The War Department weather map was recently received at the United States Signal Service office in this city. The map, which contains the United States and Canada, is divided into 20 districts or regions. Those of the Pacific States include California, Oregon and Washington Territory. The North Pacific region includes that portion of Oregon and Washington Territory west of the Cascade mountains. The Middle region, includes California, north of Monterey bay and west of the Sierra Nevada mountains, thus embracing San Francisco. The Southern region includes the remaiuing southern portion of California west of the Sierra Nevadas.

Water Wanted Everywhere.

The newspapers from the mining districts of California come to us laden with complaints about the inadequate water snpply, which, it appears, has of late heen not only insufficient to meet the needs of the miners, but, in some instances, there has heen too little for even ordinary domestic uses.

The Nevada City *Transcript*, of recent date, says that the reservoirs for furnishing that town with watsr had heen nearly empty for several days, to the great inconvenieuce of the inhabitants and the imminent exposure of the place to damage from fire; that journal, iu a subsequent issus, proceeding to remark upon the extent to which hydraulic mining in that neighborhood is crippled through this same insufficient supply of water. Nor is this complaint confined to the town and vicinage above mentioned. It is general throughout the miniug districts of the State. It comes to us from every quarter; it meets us wherever we go. It is instant and all-pervading, the expression of an urgent, universal want.

We made a flying trip last week to the interior, visiting some of the old mining camps and towns low down on the Mokelumne, near the houndary line hetween San Joaquin and Calaveras counties. These are dead places now—they died from want of water; supply them with this, and they would spring to life again, and not only regain their former prosperity, but perserve the teuure of their sxistence longer than before. Not only so; with water, new and flourishing camps would arise in localities where the diggings remain virgin, or have heen hut little exhausted, for this section of country ahounds with such. It is true, the river hars and the gulches have heen worked out. The more superficial deposits where water could he had have everywhere heen considerahly depleted. But there remain, right in this neighhorhood, where miniug was commenced at a very early day, and has since been actively continued, in so far as there has heen water for carrying it on, heavy hanks of rich gravel hardly yet touched; deep-lying heds of auriferous cement; old channels full of undisturhed wealth, with thousands of acres of shallow diggings easily worked, and sure to pay if only water were brought upon them.

Lct it be ohserved, too, that we are speaking now of a comparatively ohscure locality—of mines away down in the foothills, just on the lower edge of the main gold helt—of localities concerning which we hear hut little now-a-days. Lancha Plana, Poverty Bar and Comanche were formerly famous mining camps, though not much is said ahout them of late. Still, therc is a great extent of good mining grouud at or near these places. The hills around them are full of gold, the diggings heing often shallow and easily worked. What ie known as the sand ridge, extending for six or eight miles along the eouth side of the Mokelumne, forming, in fact, the hank of that river, is composed wholly of gold-hearing gravel, that would pay enormously if worked hy the hydraulic method with even a moderate amount of water. Some of this ground has well rewarded the labor of drifting, and a great deal of it would, no douht, do so. Then there is Cat Camp, lying off a mile or two to the south, where a thousand men might earn for themselves fair wages, if they had water for piping. All through this region a multitude of men might find employment, or rather employ themselves, if this one great want could be supplied to them.

And not in the mines alone could an increased water supply hé used here to advantage. There is a supurb farming country below them with an equally fine fruit-growing district all ahout them that stands much in need of increased irrigation facilities, their means in this respsct heing wholly inadequate to present, saying nothing of prospective requirements. It is hardly too much to say that the value of property throughout this entire region—that is, its productive capacities—would he enhanced fully 50% were it furuished with even a moderate supply of water.

From the prevailing dearth of this life-giving element, it would naturally be inferred that it was not to be had, certainly not withiu easy reach. And yet there is plenty of it; plenty, in fact, that, at a small cost, could be made practically available for every purpose. There is at this moment running to waste in the Mokelumne river 100,000 miners' inches of water, possihly twice that amount. It flows, as it ever has been suffered to flow, right through this splendid region, so full of resources and possihilities, without auy efforts having been made, or at least consummated, for its diversion and employment in ths development of this natural wealth and the creation of new industries. An association was organized a few years ago, known as the Mokelumne Ditch and Irrigation Company, for the purpose of building a ditch, through which to introduce a portion of this water upon the farming and mining lands along the south side of the river; the scope of country intcnded to he covered hy their operations reaching south to the Calaveras river and west to the tule land, the whole comprising an area of 300,000 acres. This company, which is made up of leading farmers residing iu the district and some of the prominent business men of Stockton, having first secured a franchise to 100,000 miners' inches of the water flowing in the Mokelumne river, proceeded to construct a substantial dam across that stream; their expenditures to date for improvements made, right of way ohtained, etc., amounting to something liks $75,000 or $80,000. They are already now to commence huilding their ditch, for the accomplishment of which they require some pecuniary aid—$100,000 or thereahouts. As security for a loan to that amount they propose giving a lien upon their corporate properties and possessions, water privilege and right of way included, with such other guarantees as would make the loan ahsolutely safe. They want the money for a term of years and are willing to pay a fair hut not an exorhitant rate of interest, as they should not, in view of the unexceptionally good security they are ahle to give. The money could bs obtained near home, but the rates of interest required are too high to meet the views of men engaged in such a legitimate and purely husiness-like enterprise, and the success of which they would not like to imperil hy any unnecessary hurdens. Besides, it is their purpose to furnish this water, when ready for delivery, to their patrons at ths lowest possihle rates; a policy that would hardly be feasihle if they have themselves to pay usurious interest for the use of money to carry out their project. It seems to us that our home capitalists, and others having money to loan, ought to find in this offer of ths company a good opening for placing some of their surplus funds. If there is on this coast any more valuahle species of property than a water franchise like this, we have yet to learn what it is; or if there is any other class of improvements calculated to confer greater or more lasting henefits upon the entire community than the project here alluded to, we are alike ignorant of its character. Of all the enterprises that invite capital, these ditch schemes are the most heneficent and entirely safe. Our supreme want in California is a cheap and ample water supply. This need is an ever-present exigency—urgent and incessant. Our requirements in this dirsctiou are many and multifarious, and they are constantly increasing. They grow with our growth and multiply with our population and new industries. We may be said to he forever suffering from drouth iu eome shape—a sort of perpetual water famine.

Let Our Miners Stop and Make Homes.

The epoch of the mining tramp has about passed away. The *stampede* has become a legend of the past. Those sweeping and impulsive movements that formerly carried the masses away to some far off locality—the more distant and difficult of access the hetter, have ahout subsided, or occur now only in a mild and suhdued form. They were, for the most part, ill-advised and senseless even in their hest days—these flighty movements of the multitude—seeing our miuing districts prcsent everywhere ahout an average amount of advantages, taken as a whole. Nothing tends to show this more conclusively than the fact that so many of our miners after leaving the sites of present labor, wherever they may have been, and going off after these reported "hig things," find their way hack after awhile to their starting point, satisfied there to remain; their acquaintance with the old diggings, and the home-like feeling that comes to them on getting hack among former scenes and acquaintances, more than compensating for any advantages they could hope elsewhere to enjoy. It is, indeed, the case that there is eo much in any and every part of the mining regions of this coast that ought to satisfy the man in pursuit of a pleasaut and remunerative field of labor to stop and be contented wherever his fortunes or enterprise may happen to cast him, that it is strange that any should fail to see the matter in that light.

Let the miner then tarry just where he is and there go to work cheerfully and resolutely, making the most of the opportunities around. Having secured a mine or some sort of interest in a mining property, let him next get hold of some land, the best within easy reach, and on it establish a house, improving it and gathering about him as many conveniences and comforts as possible. To this end fruit trees ehould be planted, a garden be cultivated, some land for grain-growiug be enclosed, a cow or two, soms chickens, and a team perhaps being added to his domestic establishment. If his means he limited, he has only to set to work at once, beginning in a small way, and he will himself be astonished at the rapidity with which he will get ahead. The most of the work required for accomplishing all this can he put in at odd spells, so that he will really loose very little valuable time in the end. In most parts of California there occur periods during the year when the miner cannot work his claim to advantage. In some localities this will he owing to the deep snow of winter, in others to the lack of water in the summer; the miner, through a variety of causes, having always more or less leisure for securing and improving a homestead. Let him be careful then to employ these spare hours in working for the end indicated, for they will form not only very pleasant places of abode hut also really valuahle properties by and by—these little planted patches and rude homes in the mountains.

Now, while the old-fashioned craze that sufficed to empty the population of one locality suddenly into another, has so mauifestly abated, it is still the case, that the average miner, when he reads in the papers (and he is a much reading man) ahout the big ore-finds reported here, there, and elsewhere, is apt to grow restive, and despite his past experience, itches to try his fortune ones more in this new-found El Dorado; the chances heing almost even that the evil one will put it into his head to roll up his hlankets, lock the door of his cahin, and join the rush in search of this "Kidd's Treasure," wherever rumor may happen to have planted it. And thus it is that this class of men, loosing sight of the doctrine ahove enunciated, that one ssction of the mines is, ou an average, as good as another, and disregarding the truth of the old adage ahout the rolling stone, have generally remained poor in the midst of illimitahle wealth, and restless though surrounded hy the most splendid opportunities. It is tims for them to wholly suppress this migratory spirit; stop where they are, make homes, cultivate a feeling of contentment and leave these outside opportunities, always so far off and generally so delusive, for another and less experienced class of adventurers.

The Camel on the Pacific Coast.

The first, and we helieve the only lot of camels ever hrought west of the Rocky mountains, was a hsrd of soms dozcn or more that arrived in Nevada from Texas, in 1861. They were originally brought out for the purposs of packing salt from Teel's marsh for the use of ths Washos silver mill. This marsh, then supposed to he the only saline in the State, is located in Esmeralda county, nearly 200 miles from Virginia City, the country hetween these points heing dry, desert and sandy. As salt was an indispcnsable article in the reduction of these silver-hearing ores, the millmen had hefore this been compelled to import it at heavy cost from San Francisco. The introduction of the camel into the country for salt packing from a point so remote and difficult of access, was, as suhsequent experience showed, a hit of good economy; the price of this commodity having, in consequcnce thereof, heen reduced from a hundred dollars or more per ton to ahout one-third that amount. After a year or two a more abundant deposit of salt, and of a hetter quality, was discovered near Sand Springs, Churchill county, and distant from Virginia City only 75 miles, the most of the country to he traversed being favorable for wagon transportation. From this time on tcams were employed for hauling in salt, and the use of the camels for this service having heen superseded, these animals were turued adrift upon the deserts where they were left to shift for themselves, having afterwarde been used only at intervals for packing to soms distant and out-of-the-way mining camp, or other locality, not easily reached by wagous.

After this partial ahandoument, these creatures, already terribly galled and hrokeu down through overloading and bad usage, hegan to recuperate and increase, a number of young ones having heen horn during the next few ycars; and before they left the State, which it seems thcy afterwards did, having heen driven to Arizona. We had lost sight of these "ships of the desert," not having, for a number of years, heard anything ahout them. It appears, however, as we gather from the Yuma *Sentinel* of Arizona, that they were some two years ago taken to that Territory, in the hope that they might there he profitably employed; as one would naturally expect would he the case, in view of the arid, barren and sandy character of the country to be traversed. But here again, as in Nevada, these "ships" seem to have heen stranded on the reef of disappointment. Their owners could not make them pay, the teamsters, even in that arid and sterile region, being ahle to carry freights cheaper than they; wherefore the hrutes were again turned out to shift for themselves, the owners having let them looss on the Gila eastward from Yuma, where they have been running unlooked-after ever since; and of course thriving and multiplying as is their wont when uncared-for by man. Nothing seems to suit the creature like being let alone. This ie especially the case if the looking after is to come from the average Mexican or American, who have, seemingly, neither the patience uor judgment to deal with him properly. We well remember how shamefully these docile creatures were overtasked and maltreated in Nevada, eome of them having died from their heatings and overhurdens, and we ars sorry to see that they have fared but little hetter in Arizona. The teamstere and packere there have heen making targets of them on eight, the excuse for this inhumane practice heing that they startle and even frighten by their ungainly appearance the horses, mulee and donkeys of these worthy people. Thie is, of course, good reason for sending a hullet through the unsightly hrutes whenever they are so careless as to make their appearance.

It is well now for these animals, especially the camel, that the railroad up the Gila carries everything heyond his present place of sojourn, thereby superseding the necessity for employing draft and pack animals along this part of the ronte, and, inferentially, also their drivers. It is to be hoped now that the hides of the inoffensive bcasts will no longer he punctured by the deadly missel of the "bnllwhacker" or the pilot of the "prairie schooner," but that they will be suffered to browse on the luxurious cactus and propagate in peace, their backs unchaffed by the galling pack, till such time as their services will bc required ou the sterile and waterless deserts of southeastern Arizona and the regions beyond.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

NON-CORRODIBLE MATERIAL FOR QUICKSILVER CONDENSERS.—H. H. Eames, S. F.—Dated, January 28th.—In the separation of mercury from its ores, considerable quantities of sulphurous and sulphuric acids are produced, and these acids act with great energy upon iron condensers, so that in a short time they are rendered useless. This destructive action does not take place in the first two or three of the condensers, as these are comparatively hot, but as the aqueous vapors condense, the action commences and they attack the iron with great energy. To remedy this difficulty, Mr. Eames employs a material which will resist the attack of acids and other destructive substances, and the condensers may either be constructed entirely of this material or lined with the material; or it may be employed in the form of partitions or plates, either with or without perforations to arrest the mercurial vapors. In some cases it may be found advisable to make a foundation of iron or other material, and this foundation coated with the compound. By means of this compound, the inventor forms a perfect resisting surface to the action of acids and vapors, and a mercurial condenser is made which is affective at the lower temperatures and where the aqueous vapors begin to condense. It is easily constructed on the spot and may be repaired without difficulty. Mr. Eames has used this compound for some time with great success, and one of the large brick condensers at the New Almaden mine has been lined with it recently and is now in use.

INDICATING APPARATUS.—Hans Bebr, Virginia City, Nev. Dated, Jan. 28th, 1879. This invention relates to that class of indicators which are used in hoisting or winding engines to indicate to the engineer the position of the cage in the shaft. A drum carrying a helix is mounted on a shaft operated by the main shaft, on which the reel carrying the rope and cage is mounted, said helix having marks or numbers on it corresponding to the position of cage in shaft. The revolution of the shaft carrying drum and helix operates two screw shafts which carry an indicating bar and pointer, said bar and pointer moving in a plane in the direction of the axis of the drum and following the helix, so as to point out the position of the cage on the end of the rope in the main shaft. This apparatus has recently been put in use on the Comstock, and we described it in detail a few weeks since in speaking of the machinery for the North Con. Virginia mine, which was made at the Union Iron Works in this city. It is the best improvement in this line yet devised.

ATTACHMENT FOR BOTTLE FASTENINGS.—Stephen Martinelli, Watsonville.—Dated, Jan. 28th.—This invention relates to a novel attachment to the fastenings of bottles, such as are employed to hold the corks in place where effervescing liquids are confined. These fastenings consist of a curved metal cork, so hinged at the sides of the bottle neck, as to swing over the cork to retain it in place after the bottle is filled, and they are pulled to one side when it is desired to remove the cork. It is often very difficult to remove these fastenings, as they become embedded in the cork by the internal pressure. This invention consists in the employment of a lever attachment to the link or fastening, so that the inventor is enabled to overcome any strain and remove the fastening at any time, with very little effort.

STEP LADDER.—E. W. Benjamin, S. F.—Dated, Jan. 28th.—This invention in step ladders consists in arranging a slide so as to move in grooves on the supports or bracing standards; said slide being also suitably attached to the steps by means of arms, so that when the supports are extended the arms hold the slide firmly, thus uniting the steps and the supports solidly together, and preventing any liability of the ladder shutting up. A cord attached to the slide leads to a ring or pulley on the top of the step, by means of which the slide may be moved up in its grooves, and the supports or standard thus brought back against the steps, leaving the ladder on a compact form when not in use.

JEWELRY.—Robt. W. Edwards, S. F.—Dated, Jan. 28th.—This invention relates to certain improvements in jewelry, and it consists in a novel method of forming rings, pins, bracelets, earrings and similar articles, so that the ornamental seal, brooch or pendant may be reversed to give a different front at pleasure with the same frame or ring.

JOHN O. WINSHIP, a lawyer, and Postmaster Sweet, of Windham, Oregon, have been sentenced each to $1,000 fine and one year in the county jail for conspiring to defraud their creditors.

THE rafting of logs on Eel river this winter has been attended with success.

The North Bloomfield Gravel Mining Co.

We have received the annual report to the stockholders, of the North Bloomfield Gravel Mining Co., with a statement of accounts from October 1872, to December 31st, 1878. The superintendent of this company is Henry C. Perkins, and the general manager, Mr. Hamilton Smith, Jr., the well-known hydraulic mining engineer. The report is, like all previous ones of this company, prepared with the greatest care and detail, and will serve as a model for mine reports. There are a great many interesting facts in this report, from which we condense the following:

Washing was commenced at the North Bloomfield mine on January 12th, 1878, and continued until October 10th, when the annual clean-up was made. After this clean-up only 40,000 inches of water were used in November and December. In this report a miners' inch is always assumed per a flow of 24 hours, being equivalent to a discharge of 2,230 cubic feet of water.

The following statement shows the amounts of bullion produced, and water used for 1870 to the close of 1878:

Time.	Inches used.	Yield per inch.	Gross product.
1870–4	710,987	13.6	$ 90,700.00
1874–5	386.972	19.2	74,271.77
1775–6	700,000	27.5	192,735.73
1876–7	595,000	48.9	290,775.42
1877–8	796,449	39.1	311,276.70

During the past season more water was used and more bullion produced than for any previous year. The yield per inch was 39 1-10 cents as against 48 9-10 cents in 1877. This diminution of yield has been chiefly due to the comparative poverty of the gravel channel worked last year. The main tunnel has been extended from No. 7 shaft about 1,300 feet and connected with the workings by shaft No. 9. A sluice has been placed in this extension, and hereafter all the up-stream gravel will be washed through it. The cost of this extension and new shaft amounted in 14 months to $27,896.

The tunnel was extended in nine months 1006 feet, with a section of nine feet square. Burleigh drills, driven by a Burleigh compressor, were used. The progress made averaged 112 feet per month at a cost of $24 per foot, including a full allowance for wear and tear of machinery and superintendence. Only one shift of drillers was employed; by increasing the number of workmen, probably 175 feet would have been driven each month, at about the same cost per foot. Previous to the use of these drills, three shifts of miners in the same tunnel averaged a speed of 25 feet per month, at a cost of $27 per foot.

Up to this time about 10,000,000 cubic yards of gravel have been washed through the Bloomfield Tunnel over its natural or bedrock floor, but the resulting wear has in no way impaired its usefulness.

The cost per inch of water during the last season was a trifle over two and a half cents, or one-third less than for previous years, and being at the rate of one cent for each ten-hour inch.

The Bowman reservoir dams have been finally completed, at a cost of $15,082; making a total cost of $96,640 as cost of enlargement from the old 72-foot level. These dams are very substantial, and compare favorably as regards stability with similar large structures in other parts of the world. The reservoir will now contain 907,000,000 cubic feet of water, or 410,000 24-hour inches.

The ditch and pipe conducting the waters of Texas creek into the main canal, four miles below the Bowman reservoir, have been completed at a total cost of $23,779. The pipe is an inverted syphon 4,400 feet long, 17 inches in diameter, made of riveted plate iron, with its inlet 310 feet above outlet, and sustaining a maximum pressure of 770 feet, or 334 pounds per square inch. It discharges about 1,250 miners' inches with the full head of 310 feet.

A telephone wire has been built along the line of the works, and is found of great convenience.

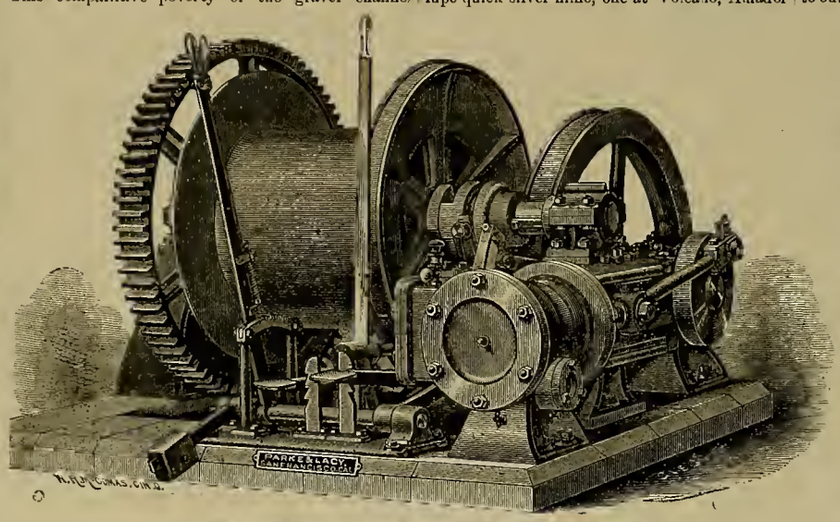
The Trustees, at the special request of the miners, decided to receive from them their surplus earnings, paying seven per cent. interest thereon: the funds derived from this source to be invested in the bonds of the company. This action was deemed advisable to inculcate saving habits in the workmen, and give them a personal interest in the company.

The completion of the Bowman dams and Texas creek pipe has finally closed the construction account of the company. For some five years past a large part of the earnings have been spent in this way. The manager considers that the outlook for future profits are very favorable, as a constant water supply is now assured for the entire year, except in very exceptionally dry seasons.

The tables accompanying this report show the expenses, etc., of the mine in the greatest detail, and are very carefully prepared. Items of mining cost, water cost, yield, profits, etc., are given in tables which show plainly the proportions of all with relation to each other.

An Improved Hoisting Engine.

The accompanying engraving represents the Niles improved hoisting engine for mining purposes. These engines are made double with single drum, double engines with double drum, and single engines with double drum, geared to suit requirements. They are made for surface or underground work, and to be run by steam or air. Messrs. Parke & Lacy, the agents, have put several of this type of hoists in operation in this State, one pair of 8x12 being at the Guadalupe quick silver mine, one at Volcano, Amador county, etc. These engines are very compact, and as the gearing is all cut they are noiseless in running. The engraving shows a 10x12 engine. This engine will hoist 2,500 pounds 1,000 feet with 60 pounds of air.



THE NILES IMPROVED MINING HOIST ENGINE.

POSTAGE ON NEWSPAPER ARTICLES.—We never could quite understand why matter written for a book should be carried in the mail for one cent an ounce, while matter written for a newspaper should be charged six cents. The public certainly has more interest in articles written for newspapers than for books, and if any favor is to be shown it should be on the side in which the public has the greatest interest. There is a chance that at least the discrimination against newspaper articles may be removed, for we read in the *Prairie Farmer* that a bill before Congress, introduced by Representative Carlisle, of Kentucky, among other things, provides that hereafter all manuscripts intended for publication in, and mailed to the editor or publisher of, any newspaper or periodical, issued at stated periods from a known office of publication, and all proof-sheets and corrected proof-sheets thereof, shall be included in mailable matter of the third class, and shall be charged postage at the rate of one cent for each ounce or fraction thereof, provided the same be the production of the editors of the journals, or regular or authorized correspondents or contributors. It is to be hoped it will become a law.

MR. J. S. PHILLIPS the well-known mining engineer and author of Phillips' "Explorers' Miners' and Metallurgists' Companion," has removed his chemical laboratory and general mining offices to No. 702 California street, where he is prepared to give practical instructions on mineral analysis, assaying, and the general subjects of mining and metallurgy. Mr. Phillips has been a practical operator for many years, and is now much better fitted than ever for giving instructions on the various branches. Testing and assaying are taught to prospectors for especial mountain requirements.

Vulcan Blasting Powder.

This is the name of a blasting powder well and favorably known on this coast. Until recently it was manufactured by Messrs. R. W Warren & Co., but this firm has now been succeeded by the Vulcan Powder Co., office 123 California street, in this city. The company owns two works. The first erected about four years ago near Reno, Nevada. This is the smaller of the two, covering about five acres. The number of men employed is 15; the motive power, water, capacity about one ton of powder per day. The second works were built about six months ago near San Pablo, Cal. These latter works are complete in every particular, and at their fullest capacity can turn out ten tons of powder per day. The company here owns a tract of 250 acres, 12 of which are covered by the mills, sheds and other buildings necessary in the manufacture of the powder; 20 to 30 men are constantly employed. Steam power alone is used as a motor. No sporting powder turned out, the company confining itself strictly to the manufacture of mining powders. Vulcan powder, when ready for market, is in the form of cartridges, varying from ⅝ inch to 1¼ inches in diameter, and from 4 to 8 inches in length. It is packed in cases of 10, 25, 50, and 100 pounds.

Vulcan powder is of three grades: Nos. 1, 2 and 3. No. 1, is claimed to be the strongest powder in use, its strength equalling that of liquid nitro-glycerine. No. 2, is said to be so strong that, except in the hardest rock, it answers every purpose. No. 3, is a slower powder than the other two, and more adapted to outside work and quarrying. These powders are a composition of nitro-glycerine and other explosives, which latter act as absorbant, consequently there being no inert matter, as in other "high explosives," every particle of it exert explosive force, not an iota of power being lost. Another advantage claimed, is that the materials used in its composition, being all decomposed by its explosion, nothing is left to float through the mine where the men have to breathe, and consequently inhale the dust, as is said to be the case when a non-explosive absorbant is used in the manufacture of a mining powder. As the smoke from Vulcan powder passes off quickly, the miners can soon after a blast resume work, thus saving time and expense.

As an indication of its high reputation, we are informed that it is was given the preference over all other high explosives, by the U. S. Engineering department at New York, in the "Hell Gate" excavations. On this coast it is largly used in prominent mines in California, Nevada, Montana, Idaho, Utah, Arizona, Mexico, etc., etc., also in important railroad works, and wherever a blasting powder is required.

In the new company, prominent mining men are interested, and thoroughly understanding the wants of the mining community, we have no doubt that Vulcan powder will, in the future, add to its already good reputation, as a strong, safe, uniform and reliable explosive. The officers of the company are: Hamilton Smith, Jr., President; Ralph L. Shainwald, Secretary; R. W. Warren, Manager. Directors—Hamilton Smith, Jr., R. W. Warren, L. L. Robinson, J. Baum and J. P. Pierce. Office, 123 California street.

Dangerous Things (?)

The echoes of the Giant powder explosion have not yet ceased reverberating it seems, though it is only in the fainter form of nerve tremors hy the interested public, or, perhaps, of pen throbs by those who do the writing for them. "Box" takes one of the latter to task as follows:

EDITORS PRESS:—A correspondent of the *Morning Call* has written a long article upon deadly poisons and explosions, wherein he (or she) states that "cyanide of potassium" is so dangerously destructive to life that merely sprinkling a sore or tasting it would cause death in a few minutes; and that there is a fulminate of gold with such amazing strength that even a small pill-box would contain sufficient to destroy "all London, or the largest army." Beware! for it is as dangerous to write upon a subject you do not understand as it is to handle deadly drugs. Box.

S. F., Jan. 23d, 1879.

A STRONG company has been organized for introducing a large amount of water from the Mokolumne river upon the farming lands lying between that stream and the Calaveras.

QUITE a severe earthquake shock was felt in Visalia Monday night about 12 o'clock.

HAY is selling in the fields near Bakersfield at $4 per ton.

TABLE OF CONTENTS.

EDITORIALS.—Smyth's Tree Feller; The Deep Mines of the World; Earthquakes Here and Elsewhere; Mining and Farming, 97. The Week; Water Wanted Everywhere; Let our Miners Stop and Make Homes; The Camel on the Pacific Coast, 104. Notices of Recent Patents; The North Bloomfield Gravel Mining Co.; An Improved Hoisting Engine; Vulcan Blasting Powder; Dangerous Things, 105.

ILLUSTRATIONS.—Smyth's Tree Felling and Log Sawing Machine, 97. Diagram Showing the Mean Relative Number of Sun-spots and Mean Rainfall for Thirty Years, 102. The Niles Improved Mining Hoisting Engine, 105.

MINING STOCK MARKET.—Sales at the San Francisco, California and Pacific Stock Boards, Notices of Assessments, Meetings and Dividends, 100.

MINING SUMMARY from the various counties of California, Nevada, Arizona and Idaho, 101-8.

NEWS IN BRIEF on 108 and other pages.

CORRESPONDENCE.—Steam Plowing Again, 98.

MECHANICAL PROGRESS.—Cold-Rolled Shafting; Welding Fused Iron; Hints for Inventors; Coating Metals with Platinum; Absorption of Carbonic Oxide by Living Organisms, 99.

SCIENTIFIC PROGRESS.—The Social Science Convention; Archæological Researches; The Voltaic Pencil; Evolution and Spontaneous Generation. 99.

USEFUL INFORMATION.—A New Mode of Locomotion; Frozen Fodder; Preserving Wheat; Water in Bread; Paraffine as a Lubricant; Coating Copper Plates with Iron, 103.

GOOD HEALTH.—A National Department of Public Health; Dieting for Health; Man's Age; Choral as a Counter Irritant, 103.

MISCELLANEOUS.—The Cone-bearers, or Evergreen Trees of California.—No. 4; Boiler Incrustations; Your Salt; How Money is Made from Copper in Yuba County; A Gold Mining Exhibition; Fuel from Waste, 98. What the English Think of Our State Pride; Cosmic Meteorology.—No. 4, 102-3.

The Week.

All this week we have been visited by a welcome, good old-fashioned rain, which is worth millions to us, for it brings us strong hopes of a plentiful crop. News from the hydraulic mining sections represents that they had been nearly all limited in operations through lack of water, and to them this storm will be a godsend. But little of interest has occurred in mining circles, except that the Bodie miners have struck for higher wages and forced the mills to shut down. There is some excitement in Oregon over new finds in gravel washings, and a false one in Gilroy over a fictitious silver ledge.

Political parties are waking up and striking the preliminary notes to the coming campaign. Considerable discussion is heard concerning the University land bill, now before Congress, and the facilities it affords for "grabbing."

From Africa comes the tidings that the Zulus have utterly annihilated a British army, which affords a text for Gladstone from which to preach Beaconsfield a sermon.

An indignant wail comes up from Arizona over the assignment of certain of her lands by Congress, to the Indians for a reservation.

Serious charges of corruption have been laid before the Board of Supervisors against the Board of Education and others implicated in the late school scandal.

Weather Districts.—The War Department weather map was recently received at the United States Signal Service office in this city. The map, which contains the United States and Canada, is divided into 20 districts or regions. Those of the Pacific States include California, Oregon and Washington Territory. The North Pacific region includes that portion of Oregon and Washington Territory west of the Cascade mountains. The Middle region, includes California, north of Monterey bay and west of the Sierra Nevada mountains, thus embracing San Francisco. The Southern region includes the remaining southern portion of California west of the Sierra Nevadas.

Water Wanted Everywhere.

The newspapers from the mining districts of California come to us laden with complaints about the inadequate water supply, which, it appears, has of late been not only insufficient to meet the needs of the miners, but, in some instances, there has been too little for even ordinary domestic uses.

The Nevada City *Transcript*, of recent date, says that the reservoirs for furnishing that town with water had been nearly empty for several days, to the great inconvenience of the inhabitants and the imminent exposure of the place to damage from fire; that journal, in a subsequent issue, proceeding to remark upon the extent to which hydraulic mining in that neighborhood is crippled through this same insufficient supply of water. Nor is this complaint confined to the town and vicinage above mentioned. It is general throughout the mining districts of the State. It comes to us from every quarter; it meets us wherever we go. It is instant and all-pervading, the expression of an urgent, universal want.

We made a flying trip last week to the interior, visiting some of the old mining camps and towns low down on the Mokelumne, near the boundary line between San Joaquin and Calaveras counties. These are dead places now—they died from want of water; supply them with this, and they would spring to life again, and not only regain their former prosperity, but perserve the tenure of their existence longer than before. Not only so; with water, new and flourishing camps would arise in localities where the diggings remain virgin, or have been but little exhausted, for this section of country abounds with such. It is true, the river bars and the gulches have been worked out. The more superficial deposits where water could be had have everywhere been considerably depleted. But there remain, right in this neighborhood, where mining was commenced at a very early day, and has since been actively continued, in so far as there has been water for carrying it on, heavy banks of rich gravel hardly yet touched; deep-lying beds of auriferous cement; old channels full of undisturbed wealth, with thousands of acres of shallow diggings easily worked, and sure to pay if only water were brought upon them.

Let it be observed, too, that we are speaking now of a comparatively obscure locality—of mines away down in the foothills, just on the lower edge of the main gold belt—of localities concerning which we hear but little now-a-days. Lancha Plana, Poverty Bar and Comanche were formerly famous mining camps, though not much is said about them of late. Still, there is a great extent of good mining ground at or near these places. The hills around them are full of gold, the diggings being often shallow and easily worked. What is known as the sand ridge, extending for six or eight miles along the south side of the Mokelumne, forming, in fact, the bank of that river, is composed wholly of gold-bearing gravel, that would pay enormously if worked by the hydraulic method with even a moderate amount of water. Some of this ground has well rewarded the labor of drifting, and a great deal of it would, no doubt, do so. Then there is Cat Camp, lying off a mile or two to the south, where a thousand men might earn for themselves fair wages, if they had water for piping. All through this region a multitude of men might find employment, or rather employ themselves, if this one great want could be supplied to them.

And not in the mines alone could an increased water supply be used here to advantage. There is a supurb farming country below them with an equally fine fruit-growing district all about them that stands much in need of increased irrigation facilities, their means in this respect being wholly inadequate to present, saying nothing of prospective requirements. It is hardly too much to say that the value of property throughout this entire region—that is, its productive capacities—would be enhanced fully 50% were it furnished with even a moderate supply of water.

From the prevailing dearth of this life-giving element, it would naturally be inferred that it was not to be had, certainly not within easy reach. And yet there is plenty of it; plenty, in fact, that, at a small cost, could be made practically available for every purpose. There is at this moment running to waste in the Mokelumne river 100,000 miners' inches of water, possibly twice that amount. It flows, as it ever has been suffered to flow, right through this spleudid region, so full of resources and possibilities, without any efforts having been made, or at least consummated, for its diversion and employment in the development of this natural wealth and the creation of new industries. An association was organized a few years ago, known as the Mokelumne Ditch and Irrigation Company, for the purpose of building a ditch, through which to introduce a portion of this water upon the farming and mining lands along the south side of the river; the scope of country intended to be covered by their operations reaching south to the Calaveras river and west to the tule land, the whole comprising an area of 300,000 acres. This company, which is made up of leading farmers residing in the district and some of the prominent business men of Stockton, having first secured a franchise to 100,000 miners' inches of the water flowing in the Mokelumne river, proceeded to construct a substantial dam across that stream; their expenditures to date for improvements made, right of way obtained, etc., amounting to something like $75,000 or $80,000. They are already now to commence building their ditch, for the accomplishment of which they require some pecuniary aid—$100,000 or thereabouts. As security for a loan to that amount they propose giving a lien upon their corporate properties and possessions, water privilege and right of way included, with such other guarantees as would make the loan absolutely safe. They want the money for a term of years and are willing to pay a fair but not an exorbitaut rate of interest, as they should not, in view of the unexceptionally good security they are able to give. The money could be obtained near home, but the rates of interest required are too high to meet the views of men engaged in such a legitimate and purely business-like enterprise, and the success of which they would not like to imperil by any unnecessary burdens. Besides, it is their purpose to furnish this water, when ready for delivery, to their patrons at the lowest possible rates; a policy that would hardly be feasible if they have themselves to pay usurious interest for the use of mouey to carry out their project. It seems to us that our home capitalists, and others having money to loan, ought to find in this offer of the compauy a good opening for placing some of their surplus funds. If there is on this coast any more valuable species of property than a water franchise like this, we have yet to learn what it is; or if there is any other class of improvements calculated to confer greater or more lasting benefits upon the entire community than the project here alluded to, we are alike ignorant of its character. Of all the enterprises that invite capital, these ditch schemes are the most beneficent and entirely safe. Our supreme want in California is a cheap and ample water supply. This need is an ever-present exigency—urgent and incessant. Our requirements in this directiou are many and multifarious, and they are constantly increasing. They grow with our growth and multiply with our population and new industries. We may be said to be forever suffering from drouth in some shape—a sort of perpetual water famine.

Let Our Miners Stop and Make Homes.

The epoch of the mining tramp has about passed away. The *stampede* has become a legend of the past. Those sweeping and impulsive movements that formerly carried the masses away to some far off locality—the more distant and difficult of access the better, have about subsided, or occur uow only in a mild aud subdued form. They were, for the most part, ill-advised and senseless even in their best days—these flighty movements of the multitude—seeing our mining districts present everywhere about an average amount of advantages, taken as a whole. Nothing tends to show this more conclusively than the fact that so many of our miners after leaving the sites of present labor, wherever they may have been, and going off after these reported "big things," find their way back after awhile to their starting point, satisfied there to remain; their acquaintance with the old diggings, and the home-like feeling that comes to them on getting back amoug former scenes and acquaintances, more than compensating for any advantages they could hope elsewhere to enjoy. It is, indeed, the case that there is so much in any and every part of the mining regions of this coast that ought to satisfy the man in pursuit of a pleasaut and remunerative field of labor to stop and be contented wherever his fortunes or enterprise may happen to cast him, that it is strange that any should fail to see the matter in that light.

Let the miner then tarry just where he is and there go to work cheerfully and resolutely, making the most of the opportunities around. Having secured a mine or some sort of interest in a mining property, let him next get hold of some land, the best within easy reach, and on it establish a house, improving it and gathering about him as many couveniences and comforts as possible. To this end fruit trees should be planted, a garden be cultivated, some land for grain-growiug he enclosed, a cow or two, some chickens, aud a team perhaps being added to his domestic establishment. If his means be limited, he has only to set to work at once, beginning in a small way, and he will himself be astonished at the rapidity with which he will get ahead. The most of the work required for accomplishing all this can be put in at odd spells, so that he will really loose very little valuable time in the end. In most parts of California there occur periods during the year when the miner cannot work his claim to advantage. In some localities this will be owing to the deep snow of winter, in others to the lack of water in the summer; the miner, through a variety of causes, having always more or less leisure for securing and improving a homestead. Let him be careful then to employ these spare hours in working for the end iudicated, for they will form not only very pleasant places of abode but also really valuable properties by and by—these little planted patches and rude homes in the mountains.

Now, while the old-fashioned craze that sufficed to empty the population of one locality suddenly into another, has so manifestly abated, it is still the case, that the average miner, when he reads in the papers (and he is a much reading man) about the big ore-finds reported here, there, and elsewhere, is apt to grow restive, and despite his past experience, itches to try his fortune once more in this new-found El Dorado; the chances being almost even that the evil one will put it into his head to roll up his blankets, lock the door of his cabin, and join the rush in search of this "Kidd's Treasure," wherever rumor may happen to have planted it. And thus it is that this class of men, loosing sight of the doctrine above enunciated, that one section of the mines is, ou an average, as good as another, and disregarding the truth of the old adage about the rolling stone, have generally remained poor in the midst of illimitable wealth, and restless though surrounded by the most splendid opportunities. It is time for them to wholly suppress this migratory spirit; stop where they are, make homes, cultivate a feeling of contentment and leave these outside opportunities, always so far off and generally so delusive, for another and less experienced class of adventurers.

The Camel on the Pacific Coast.

The first, and we believe the only lot of camels ever brought west of the Rocky mountains, was a herd of some dozen or more that arrived in Nevada from Texas, in 1861. They were originally brought out for the purpose of packing salt from Teel's marsh for the use of the Washoe silver mill. This marsh, then supposed to be the only saline in the State, is located in Esmeralda county, nearly 200 miles from Virginia City, the country between these points being dry, desert and sandy. As salt was an indispensable article in the reduction of these silver-bearing ores, the millmen had before this been compelled to import it at heavy cost from San Francisco. The introduction of the camel into the country for salt packing from a point so remote and difficult of access, was, as subsequent experience showed, a bit of good economy; the price of this commodity having, in consequence thereof, been reduced from a hundred dollars or more per ton to about one-third that amount. After a year or two a more abundant deposit of salt, and of a better quality, was discovered near Saud Springs, Churchill county, and distant from Virginia City only 75 miles, the most of the country to be traversed being favorable for wagon transportation. From this time on teams were employed for hauling in salt, and the use of the camels for this service having been superseded, these animals were turned adrift upon the deserts where they were left to shift for themselves, having afterwards been used only at intervals for packing to some distant and out-of-the-way mining camp, or other locality, not easily reached by wagons.

After this partial abandonment, these creatures, already terribly galled and broken down through overloading and bad usage, began to recuperate and increase, a number of young ones having been born during the next few years; and before they left the State, which it seems they afterwards did, having been driven to Arizona. We had lost sight of these "ships of the desert," not having, for a uumber of years, heard anything about them. It appears, however, as we gather from the Yuma *Sentinel* of Arizona, that they were some two years ago taken to that Territory, in the hope that they might there be profitably employed; as one would naturally expect would be the case, in view of the arid, barren and sandy character of the country to be traversed. But here again, as in Nevada, these "ships" seem to have been stranded on the reef of disappointment. Their owners could not make them pay, the teamsters, even in that arid and sterile region, being able to carry freights cheaper than they; wherefore the brutes were again turned out to shift for themselves, the owners having let them loose on the Gila eastward from Yuma, where they have been running unlooked-after ever since; and of course thriving and multiplying as is their wont when uncared-for by man. Nothing seems to suit the creature like being let alone. This is especially the case if the looking after is to come from the average Mexican or American, who have, seemingly, neither the patience nor judgment to deal with him properly. We well remember how shamefully these docile creatures were overtasked and maltreated in Nevada, some of them having died from their beatings and overburdens, and we are sorry to see that they have fared but little better in Arizona. The teamsters and packers there have been making targets of them on sight, the excuse for this inhumane practice being that they startle and even frighten by their ungainly appearance the horses, mules and donkeys of these worthy people. This is, of course, good reason for sending a bullet through the unsightly brutes whenever they are so careless as to make their appearance.

It is well now for these animals, especially the camel, that the railroad up the Gila carries everything beyond his present place of sojourn, thereby superseding the necessity for employing draft and pack animals along this part of the route, and, inferentially, also their drivers. It is to be hoped now that the hides of the inoffensive beasts will no longer be punctured by the deadly missel of the "bullwhacker" or the pilot of the "prairie schooner," but that they will be suffered to browse on the luxurious cactus and propagate in peace, their backs unchaffed by the galling pack, till such time as their services will be required on the sterile and waterless deserts of southeastern Arizona and the regions beyond.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

NON-CORRODIBLE MATERIAL FOR QUICKSILVER CONDENSERS.—H. H. Eamee, S. F.—Dated, January 28th.—In the separatiou of mercury from its ores, considerable quantitiee of sulphurous and sulphuric acids are produced, and these acids act with great energy upon iron condensers, so that in a short time they are rendered useless. This destructive actiou does not take placc in the first two or three of the condensers, as these are comparatively hot, but as the aqueous vapore condense, the action commences and thoy attack the iron with great energy. To remedy this difficulty, Mr. Eamce employs a material which will resist the attack of acide and other destructive subetauces, aud the condensers may either be constructed entirely of thie material or liued with the material; or it may be employed in the form of partitions or plates, either with or without perforatione to arrost the mercurial vapors. In soms cases it may bo found advisable to make a feundation of iron or other material, and thie foundation coated with the compound. By means of this compound, the inventor ferms a perfect rsisting surface to the action of acide and vapors, and a mercurial condenser ie made which is affective at the lower temperatures and where the aqueous vapors begin to condenso. It is easily constructed on ths spot and may be repaired without difficulty. Mr. Eames hae used this compound for some time with great success, and one of the large brick condeneers at the New Almaden mine has been lined with it recently and ie now in use.

INDICATING APPARATUS.—Hans Behr, Virginia City, Nev. Dated, Jan. 28th, 1879. Thie invention relates to that class of indicatore which are used in hoieting or winding engines to indicate to the engineer tho position of the cage in the shaft. A drum carrying a helix is mounted on a shaft operated by the main ehaft, on which the reel carrying the rope and cage is mounted, said helix having marks or numbers on it corresponding to the position of cage in shaft. The revolution of the shaft carrying drum and helix operates two screw shafts which carry an indicating bar and pointer, said bar and pointer moving in a plane in the direction of the axie of the drum and following the helix, so as to point out the poeition of the cage on the end of the rope in the main ehaft. This apparatus has recently been put in use on the Comstock, and we described it in detail a few weeke eince iu speaking of the machinery for the North Con. Virginia mine, which was made at the Union Iron Worke in this city. It ie the best improvement in this line yet devised.

ATTACHMENT FOR BOTTLE FASTENINGS.—Stephen Martinelli, Watsouville.—Dated, Jan. 28th. — This invention relates to a novel attachment to the faetenings of bottles, such as are employed to hold the corks in place where effervescing liquids are confined. These fastenings conoist of a curved metal cork, eo hinged at the sides of the bottle neck, as to swing over the cork to retain it in place after the bottle is filled, and they are pulled to one side when it is desired to remove the cork. It is often very difficult to remove these fastenings, as they become embedded in the cork by the internal preesure. This invention consists in the employment of a lever attachment to the link or fastening, so that the inventor is enabled to overcome any strain and remove the fastening at any time, with very little effort.

STEP LADDER.—E. W. Benjamin, S. F.—Dated, Jan. 28th.—Thie invention in etep ladders consiste in arranging a elide eo as to move in grooves on the supports or bracing standards; said slide being also euitably attached to the steps by means of arms, so that when the supporte are extended the arms hold the slide firmly, thue uniting the steps and the supports solidly together, and preventing any liability of the ladder ehutting up. A cord attached to the slide leade to a ring or pulley on the top of the step, by meane of which the slide may be moved up in its grooves, and the eupports or standard thus brought back againet the steps, leaving the ladder on a compact form when not in use.

JEWELRY.—Robt. W. Edwarde, S. F.—Dated, Jan. 28th.—This invention relates to certain improvements in jewelry, and it consists in a novel mothod of forming rings, pine, bracelets, earrings and similar articles, so that the ornamental eoal, brouch or pendant may be reversed to give a different front at pleasure with the same frame or ring.

JOHN O. WINSHIP, a lawyer, and Postmaster Sweet, of Windham, Oregou, have been sentenced each to $1,000 fine and oue year in the county jail for conspiring to defraud their creditore.

THE rafting of logs on Eel river thie winter has been attended with euccess.

The North Bloomfield Gravel Mining Co.

We have received the annual report to the stockholders, of the North Bloomfield Gravel Mining Co., with a statement of accounts from October 1872, to December 31st, 1878. The euperintendent of this company is Henry G. Perkins, and the general manager, Mr. Hamilton Smith, Jr., the well-known hydraulic mining engineer. The report is, like all previous ones of this company, prepared with the greatest care aud detail, and will serve as a model for mine reporte. There are a great many interesting facts in this report, from which we condense the following:

Washing was commenced at the North Bloomfield mine ou January 12th, 1878, and coutinued until October 10th, when the annual clean-up was made. After this clean-up only 40,000 iuches of water were used in November and December. In this report a miners' iuch is always assumed per a flow of 24 hours, being equivalent to a discharge of 2,230 cubic feet of water.

The following statement ehows the amounts of bulhon produced, and water used for 1870 to the closc of 1878:

Time.	Inches used.	Yield per inch.	Gross product.
1870–4	710,987	13.6	$ 96,700.00
1874–5	386.972	19.2	74,271.77
1775–6	700,000	27.5	192,735.73
1876–7	595,000	48.9	290,775.42
1877–8	796,449	39.1	311,276.70

During the past season more water was used and more bullion produced than for any previous year. The yield per iuch was 39 1-10 cents as against 48 9-10 cents in 1877. Thie diminution of yield has been chiefly due to the comparative poverty of the gravel channel worked last year. The maiu tunuel has been extended from No. 7 shaft about 1,300 feet and connected with the workings by shaft No. 9. A eluice has been placed iu this extension, and hereafter all the up-stream gravel will be washed through it. The coet of this extension and new shaft amounted iu 14 months to $27,896.

The tunnel was extended in nine months 1006 feet, with a section of nine feet square. Burleigh drills, driven by a Burleigh compressor, were used. The progress made averaged 112 feet per month at a cost of $24 per foot, includiug a full allowance for wear and tear of machinery and superintendence. Only one shift of drillers was employed; by increasing the nnmber of workmen, probably 175 feet would have been driven each month, at about the eame coet per foot. Previous to the uee of these drills, three shifts of miners in the same tunnel averaged a speed of 25 feet per month, at a cost of $27 per foot.

Up to this time about 10,000,000 cubic yards of gravel have been washed through the Bloomfield Tunnel over its natural or bedrock floor, but the resulting wear has iu no way impaired its usefnlness.

The coet per inch of water during the last season was a trifle over two and a half ceuts, or one-third less than for previoue years, and being at the rate of one cent for each ten-hour inch.

The Bowman reservoir dams have been finally completed, at a cost of $15,082; making a total cost of $96,640 as cost of enlargement from the old 72-foot level. These dams are very substantial, and compare favorably as regards stability with similar large structurcs in other parte of the world. The reservoir will now contain 907,000,000 cubic feet of water, or 410,000 24-hour inches.

The ditch and pipe conducting the waters of Texas creek into the main canal, four miles below the Bowman reservoir, have been completed at a total cost of $23,779. The pipe is an inverted syphon 4,400 feet long, 17 inches in diameter, made of riveted plate iron, with its inlet 310 feet above outlet, and enetaining a maximum preseure of 770 feet, or 334 pounds per square inch. It discharges about 1,250 miners' inches with the full head of 310 feet.

A telephone wire has been built along the line of the works, and is found of great convenience.

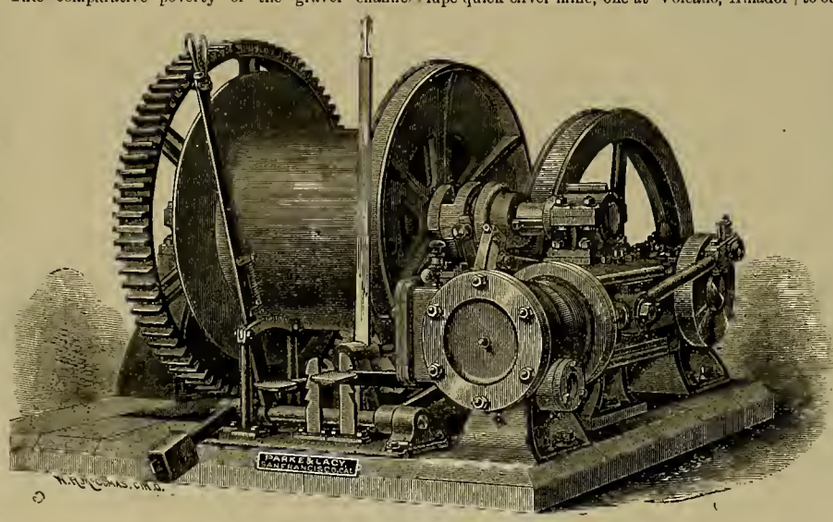
The Trustees, at the special request of the miners, decided to receive from them their surplus earnings, paying seven per cent. interest therson: the funde derived from this eource to be invested in the bonds of the company. Thie action was deemed advisable to inculcate saving habits in the workmen, and give them a personal interest in the company.

The completion of the Bowman dams and Texas creek pipe hae finally closed the construction account of the company. For eeme five years past a largo part of the earnings have been epent in thie way. The manager conceiders that the outlook for future profits are very favorable, ae a constant water supply is now assured for the entire year, except in very exceptionally dry seasons.

The tables accompanying this report show the expenees, etc., of the mine in the greatest detail, and are very carefully prepared. Items of mining cost, water cost, yield, profite, etc., are given in tables which show plainly the proportions of all with relation to each other.

An Improved Hoisting Engine.

Tho accompanying engraving represents the Niles improved hoisting engine for mining purposes. Theso engines are made double with single drum, double engines with double drum, and single engines with double drum, geared to suit requirements. They are made for surface or underground work, and to be run by steam or air. Messrs. Parke & Lacy, the agents, have put several of this type of hoists in operation in this State, one pair of 8x12 being at the Guadalupe quick silver mine, one at Volcano, Amador county, etc. These engines are very compact, and as the gearing ie all cut they are noiseless in running. The engraving shows a 10x12 engine. This engine will hoist 2,500 pounds 1,000 feet with 60 pounde of air.



THE NILES IMPROVED MINING HOIST ENGINE.

POSTAGE ON NEWSPAPER ARTICLES.—We never could quite understand why matter written for a book should be carried in the mail for one cent an ounce, while matter written for a newspaper should be charged six cents. The public certainly has more intereet in articles written for newspapers than for books, aud if any favor is to be shown it should be on the side in which the public bas the greatest interest. There is a chance that at least the discrimination against newspaper articles may be removed, for we read in the *Prairie Farmer* that a bill before Congress, introduced by Repreeentative Carlisle, of Kentucky, among other things, provides that hereafter all manuscripts intended for publication in, and mailed to the editor or publisher of, any newspaper or periodical, iesued at etated periode from a known office of publication, and all proof-sheets and corrected proof-sheets thereof, shall be included in mailable matter of the third class, and shall be charged poetage at the rate of one cent for each ounce or fraction thereof, provided the same be the production of the editors of the journale, or regular or authorized correspondents or contributors. It is to be hoped it will become a law.

MR. J. S. PHILLIPS the well-known mining engineer and author of Phillips' "Explorers' Miners' and Metallurgists' Companion," has removed his chemical laboratory and general mining offices to No. 702 California etreet, where he is prepared to give practical instructions on mineral analysis, assaying, and the general subjects of mining and metallurgy. Mr. Phillips has been a practical operator for many years, and is now much better fitted than ever for giving instructioue on the various branches. Testing and assaying are taught to prospectors for especial mountain requirements.

Vulcan Blasting Powder.

This is the name of a blasting powder well and favorably known on this coast. Until recently it was manufactured by Messrs. R. W Warren & Co., but this firm has now been succeeded by the Vulcan Powder Co., office 123 California street, in this city. The company owns two worke. The first erected about four years ago near Reno, Nevada. This is the smaller of the two, covering about five acres. The number of men employed is 15; the motive power, water; capacity about one ten of powder per day. The eecond worke were built about six months ago near San Pablo, Cal. These latter works are complete in every particular, and at their fullest capacity can turn out ten tons of powder per day. The company here owns a tract of 250 acres, 12 of which are covered by the mills, sheds and other buildings necessary in the manufacture of the powder; 20 to 30 men are constantly employed. Steam power alone is used as a motor. No eporting powder turned out, the company confining itself strictly to the manufacture of mining powders. Vulcan powdor, when ready for market, is in the form of cartridges, varying from ⅝ inch to 1¼ inches in diameter, and from 4 to 8 inches in length. It is packed in cases of 10, 25, 50, and 100 pounds.

Vulcan powder ie of three grades: Nos. 1, 2 and 3. No. I, is claimed to be the strongeet powder in uee, its streugth equalling that of liquid nitro-glyceriue. No. 2, is said to be so strong that, except in the hardest rock, it answers every purpose. No. 3, ie a slower powder than the other two, and more adapted to outside work and quarrying. These powders are a compoeition of nitro-glycerine and other explosives, which latter act as absorbant, consequeutly there being no inert matter, as in other "high explosives," every particle of it exert explosive force, not an iota of power being loet. Another advantage claimed, is that the materiale ueed in ite compositiou, being all decomposed by its explosion, nothing is left to float through the mine where the men have to breathe, and consequently inhale the dust, as is said to bo the case wheu a non-explosive absorbant is used in the manufacture of a mining powder. Ae the emoke from Vulcan powder passes off quickly, the minere can soon after a blaet resume work, thus saving time and expenso.

As an indicatiou of its high reputation, we are informed that it is wae given the preference over all other high explosives, by the U. S. Engineering department at New York, in the "Hell Gate" excavations. On thie coast it ie largly used in prominent mines in California, Nevada, Montana, Idaho, Utah, Arizoua, Mexico, etc., etc., also in important railroad works, and wherever a blaeting powder ie required.

Iu the new company, prominent mining men are interested, and thoroughly understanding the wants of the mining community, we have no doubt that Vulcan powder will, in the future, add to its already good reputation, as a strong, safe, uniform and reliable explosive. The officers of the company are: Hamilton Smith, Jr., President; Ralph L. Shainwald, Secretary; R. W. Warren, Manager. Directors—Hamilton Smith, Jr., R. W. Warren, L. L. Robinson, J. Baum and J. P. Pierce. Office, 123 California etreet.

Dangerous Things (?)

The echoes of the Giant powder explosion have not yet ceased reverberating it seems, though it is only in the fainter form of nerve tremore by the interested public, or, perhaps, of pen throbs by those who do the writing for them. "Box" takes one of the latter to task as followe:

EDITORS PRESS:—A correspondent of the *Morning Call* has written a long article upon deadly poisons and explosions, wherein he (or she) etates that "cyanide of potassium" is so dangerously destructive to life that merely sprinkling a eore or tasting it would cause death in a few minutes; and that there is a fulminate of gold with such amazing strength that even a small pill-box would contain sufficient to destroy "all London, or the largest army." Beware! for it is as dangerous to write upon a subject you do not understand as it is to handle deadly druge. Box.

S. F., Jan. 23d, 1879.

A STRONG company has been organized for introducing a large amount of water from the Mokolumne river upon the farming lands lying between that stream and the Calaveras.

QUITE a severe earthquake shock was felt in Visalia Monday night about 12 o'clock.

HAY ie eelling in the fields near Bakersfield at $4 per ton.

FOREIGN PATENTS

FOR PACIFIC STATES INVENTORS

ARE SECURED IN MUCH LESS TIME,

—BY—

DEWEY & CO.,

AT THE OFFICE OF THE

Mining and Scientific Press,

THAN THROUGH ANY OTHER AGENCY.

Established in 1860,

THIS FIRM CAN BE RELIED UPON

—AS—

Honest, Competent, Permanent,

ALL OF WHICH POINTS ARE IMPERATIVELY REQUISITE IN ATTORNEYS, FOR THE INTERESTS OF THEIR APPLICANTS FOR PATENTS IN DISTANT LANDS.

Our Associates and Correspondents are the Best Practitioners in every country where Patents are granted.

For Foreign Patents no model is required, as a rule, except in Canada. The Specifications and Drawings of the American Patent, if complete and perfect, will suffice for us to prepare the case. In Great Britain and other countries we apply for patents in the inventors' own names, thus avoiding their being published to the world in the name of a foreign agent, as is usual through other and less painstaking agencies.

Frequently several inventions, covered by different patents in the United States, on the same subject, can be skillfully combined in one patent in foreign countries, when well understood by intelligent attorneys.

As the privileges of our inventors are cut off in *some* countries, and curtailed in others, if not applied for soon after the issue of the U. S. patent, we advise inventors whose patents will be valuable in various populous civilized countries, to lose no time in applying for patents whenever they intend to obtain them for themselves or the benefit of others—with their own means or through the resources of those who are permitted to share the benefits. It must be remembered that the English (and some other important nations) invite the early introduction of inventions into their realms, by offering patents to the first *introducer* (which means the first *applicant*), without regard to the rights of the *actual* inventor, who has no after recourse.

For important inventions it is best to apply for foreign patents at the time of application for or before the issue of the U. S. patent.

Term of Patents in Foreign Countries

COUNTRIES.	PERIOD OF YEARS GRANTED, ETC.
Australian Colonies: Victoria	14 years in successive periods, 3, 4 & 7 yrs.
Tasmania	14 years in successive periods, 3, 4 & 7 yrs.
New South Wales	7 to 14 years.
Queensland	7 to 14 years.
New Zealand	Full term, 14 years.
Austria	15 years, by annuities.
Argentine Republic	25 years or more, determined by gov't.
Belgium	20 years by annuities.
Brazil	5 to 20 years.
Canada, (including British Columbia)	14 years.
Chile	25 years or more, determined by gov't.
Cuba	5, 10 and 15 years.
Denmark	5 to 20 years, at the option of government.
England	14 years, in successive periods, 3, 4 & 7 yrs.
France	15 years, by annuities.
German Empire	15 years.
Italy	12 years, by annuities.
India	14 years, 5 copies, specification required.
Mexico	Full term, 10 years.
Norway	5 to 10 years, at the option of gov't.
Portugal	Importation 5, Invention 15 years.
Peru	25 years or more, determined by gov't.
Russia	Importation 1 to 6 yrs, Invent'n, 3, 3, 10 yrs.
Spain	Importation, 5 yrs. Invention 5, 10, 15 yrs.
Sweden	3 to 5 yrs, at the option of government.

We have the Foreign Patent Laws, Foreign Patent Reports, and other valuable and assisting documents, for ready reference in our MINING AND SCIENTIFIC PRESS Patent Agency Library—the most complete Patent Library on this side of the Continent.

The cost of patents in any one or more of the above countries will be furnished on application to us.

Any further information regarding the time within which patents must be worked in any foreign country, time of payment and amount of annuities for patents in any of the above countries, will be cheerfully given on application.

Full particulars regarding any countries not named above, will also be given when desired.

DEWEY & CO., Patent Agents,

Publishers of the MINING AND SCIENTIFIC PRESS and the PACIFIC RURAL PRESS, San Francisco.

ABOUT SECURING U. S. COPYRIGHTS, TRADEMARKS, LABELS, Etc.

[Under the Revised Act of Congress, which took effect August 1st, 1874.]

No copyright is valid unless notice is given by inserting in every copy published, on the title page or the page following, if it be a book; or, if a map, chart, musical composition, print, cut, engraving, photograph, painting, drawing, chromo, statue, statuary, or model or design intended to be perfected as a work of the fine arts, by inscribing upon some portion thereof, or on the substance on which the same is mounted, the following words, viz.: "*Entered according to the act of Congress, in the year ——, by ——, in the office of the Librarian of Congress, at Washington;*" or, at the option of the person entering the copyright, the words: "*Copyright, 18—— by ——*"

The law imposes a penalty of $100 upon any person who has not obtained copyright who shall insert the notice "*Entered according to act of Congress,*" or "*Copyright,*" etc., or words of the same import, in or upon any book or other article.

Each copyright secures the exclusive right of publishing the book or article copyrighted for the term of 28 years. Six months before the end of that time, the author of designer, or his widow or children, may secure a renewal for the further term of 14 years, making 42 years in all. Applications for renewal must be accompanied by explicit statement of ownership, in the case of the author, or of relationship, in the case of his heirs, and must state definitely the date and place of entry of the original copyright.

[Our terms for securing a copyright certificate is $5, including the Government fee.]

[Our terms for securing certificate of registration for a label is $16, including Government fee.]

Copyrights cannot be granted upon trademarks, nor upon labels intended to be used with any article of manufacture. If protection for such prints or labels is desired, application must be made to the Patent Office, where they are registered at a fee of $6 for labels and $25 for trademarks.

Applicants for the registration of trademarks must file the following papers in the Patent office, to wit:

1. A specification fully describing the trademark.
2. A petition by the party or firm.
3. An oath by some member of the firm, if it be a firm; otherwise by the owner.

[Our terms for securing the registration of a trademark (issued in the form of a patent) is $40, including Government fees.]

If you have a label which you desire to protect against imitation, you can have this done by complying with the following rules, viz.:

1. Send us six copies of the label, and full name of proprietor.
2. State the class of goods to be protected, and give a brief description of your business.

For further information concerning the above, U. S. and Foreign Patents, Caveats and general patent soliciting business, address

DEWEY & CO., S. F.

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued, wholesale and retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS Office, S. F.

BY GUIDO KUSTEL,
MINING ENGINEER AND METALLURGIST.

Roasting of Gold and Silver Ores, and the Extraction of their respective Metals without Quicksilver. 1870.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore.

It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus.

It is a work of great merit, by an author whose reputation is unsurpassed in his specialty.

Price, $2.50 coin, postage free.

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulpburets, Arseniurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867.

This work is unequaled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Millman, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery, etc., which alone are of the greatest value. PRICE, $7.5

Much Obliged, Etc.

PORTLAND, OREGON, June 26th, 1877.

DEWEY & Co., Patent Solicitors, S. F.—*Gents:* I am much obliged to you for courtesy shown me, and am much pleased with the manner in which you have done my business, and assure you, will cheerfully recommend you to my acquaintance needing such services. Hope to have a case again before long, of my own. I have been an inventor all my life, but let others reap the benefit, or had work stolen from me. Please have the extra copies of my patent, etc., mailed to me direct, and oblige

Yours truly. J. H. WOODRUM.

For drills ½ & under, 2.25
By Mail, postage, 4 & 8 cts.

Accurate, Durable. Well made and equal to the best Chucks in use.

TRUMP BROS., Mfrs., Wilmington, Del., U. S. A.

Barlow J. Smith, M. D.

Consulting Physician,

Professor of Phrenology and Mental Hygiene.

Proprietor of the Smithsonian Medical and Phrenological Institute, 635 California Street, above Kearny.

This Institute, by combining medical hygiene with the various Water Cure treatments and the most powerful Electrized Horseshoe Magnet in the world, claims to cure speedily and permanently all forms of acute or chronic nervo-vital derangements, Brain, Spinal and Heart diseases, St. Vitus Dance, Palsy, Epilepsy and all Rheumatic, Liver and Kidney troubles. The institution has for the past 20 years made a specialty of treating all forms of weaknesses and diseases peculiar to males and females. By the use of hygienic remedies and electro-motopathy the worst forms of impotency and seminal weakness in males and sterility in females are speedily and permanently overcome. Hygienic board, with or without rooms. Terms moderate. Electro-thermal, Russo-Turkish and Medicated Baths given daily. Mrs. Dr. Smith as Matron has charge of the female bathing department.

DR. SMITH has practiced Phrenology the past 30 years, and during the last 20 years has been constantly using the science connected with Physiognomy, in examining or diagnosing disease in this city, and claims to have made discoveries in the SCIENCE of Phrenology that enables him, by an examination of the head, even blindfolded, to determine the disease to which the person is constitutionally subject, or whether the disease at the time afflicting the person, is the result of accident or hereditary weakness; whether CONSUMPTIVE, DYSPEPTIC, RHEUMATIC, APOPLECTIC, NEURALGIC, LEUCORRHŒAL or SEMINAL. Especially does the form of the head indicate the strength of the uterine, genital or reproductive system. The head is also an index of the natural strength of the lungs, heart, stomach, liver, kidneys, spleen, back or vertebra, and it determines the power of the system in warding off and overcoming disease of all kinds.

Ladies or gentlemen, desirous of obtaining a thorough and correct Phrenological examinations with Fowler and Wells' charts, will meet with a respectful reception at his consulting rooms. Parties can depend upon a reliable delineation of the character of their intimate male or female friends, by presenting a clearly defined photograph.

Phrenological or Physiognomical examinations without charts, $1.50; with charts, from $2 to $3.

INVITATION TO INVALIDS

And all persons who are in any way out of health, who desire to know the nature and causes of their disease, may avail themselves of an examination through phrenology in regard to health free of charge, between the hours of 9 A. M. and 8 P. M. Sundays from 9 A. M. to 12 M.

CAUTION
To Hydraulic Miners.

The public generally and Hydraulic Miners especially are hereby notified that any parties making or using the contrivance known as the HOSKIN DEFLECTOR will be prosecuted to the full extent of the law, said machine having been declared by the U. S. Circuit Court an infringement upon my patent, the

Bloomfield Deflecting Nozzle.

The public are also cautioned against using the Hoskin Deflector because of its danger to life and limb, this device having already occasioned several deaths and other serious accidents. The BLOOMFIELD DEFLECTOR is entirely safe, its two and a half years use without accident, as well as its construction, proves it to be a reliable contrivance.

Any parties wishing to purchase the right to use these Deflectors can do so by applying to the undersigned,

HENRY C. PERKINS,

North Bloomfield, Nevada Co., Cal., October 1st, 1878.

Assaying and Testing Taught.

Pocket Map of California and Nevada.

Compiled from the latest authentic sources, by Chas. Drayton Gibbs, C. E. This map comprises information obtained from the U. S. Coast and Land, Whitney's State Geological, and Railroad Surveys; and from the results of explorations made by R. S. Williamson, U. S. A., Henry Degroot, C. D. Gibbs and others. The scale is 18 miles to 1 inch. It gives the Judicial and U. S. Land Districts. It distinguishes the Townships and their subdivisions; the County Seats; The Military Posts; the Railroads built and proposed, and the limits of some of them; the occurrence of gold, silver, copper, quicksilver, tin, coal and oil. It has a section showing the hights of the principal mountains. The boundaries are clear and unmistakable, and the print good. 1878. Sold by DEWEY & CO. Price, postpaid, $2; to subscribers of this journal, until further notice, $1.

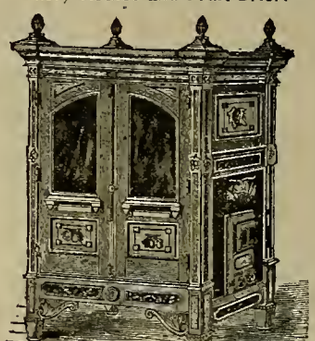
DEFLECTED HEAT!

Boswell's Combined Heater, Cooker, Baker, Clothes and Fruit Drier.



Combining the advantages of a Stove, Furnace, Oven, Dry House and Kitchen Range. An application of Scientific Principles to the economy of living, of labor, of health and of comfort. A handsome piece of Furniture adapted to the wants of every family. It equally economizes time, labor and fuel, and avoids exposure to heat in cooking as well as in baking. It bakes Bread, Cakes and Pies to any desired tint without turning or watching, or danger of burning. All odors produced in cooking are passed up the flue. Food cooked by deflected heat is improved in flavor, more easily digested, contains more nutriment, will keep fresh longer, and is also much improved in appearance. The stages of the cooking or baking can be seen without stooping or opening the doors of the oven. It will dry and bleach your clothes in from half an hour to one hour and a half, and heat your irons.

Fruit dried in the Boswell will gain from TWENTY to FORTY PER CENT. in WEIGHT, and THIRTY PER CENT. in QUALITY over that dried by any other process. It will successfully dry any kind of Fruit, Grapes, Berries, Meats, Fish, Vegetables, Coffee, Tobacco, Corn and Grain of all kinds.

— ALSO —

Boswell's Commercial Fruit Drier,

Used exclusively for drying and heating purposes ON A LARGE SCALE.

— ALSO —

BOSWELL'S CABINET HEATER,

Of all sizes and capacity for heating Private Residences, Hotels, Halls, School Houses, Churches, Offices, Stores, Railroad Cars, Hospitals, etc.

All of which can be operated successfully by a mere child, it is so simple in its construction, and with one-third the usual amount of fuel (coal or wood), used in any other heating, cooking or drying apparatus.

Every farmer and economical housekeeper should use it. It will pay for itself in the saving of fuel; it will pay in the superior character of its FRUIT DRYING, of its COOKING, ROASTING and BAKING; it will pay in its salubrious and healthful warm air; it will pay the rich and the poor alike.

Sold by DEWEY & Co., Patent Agents and publishers of MINING AND SCIENTIFIC PRESS, San Francisco. Price, $1, (post paid.

Continued from Page 101.

level, but little advance has been made owiug to a necessity for timbering. The daily yield of ore is gradually lessening, and the bullion returns for the present month ars not likely to reach the amount of the proceeds of January.

Con. Virginia.—The ore stopes on the 1500 and 1400 levels are lookiug well, and there is a steady increase in the amount of ore extracted. Sinking the C. & C. shaft is going forward at the rate of 2½ feet per day. The joint west crosscut on the 1950 level is still advancing in favorable ledge material.

Yellow Jacket.—The connection between the new shaft and the 2200 level of the old works having been made last Friday, a station is being cut out at that point. This station is the 2280 of the new shaft, the difference between the surface level of this shaft and the old one being about 80 feet. When the 2280 station of the new shaft is completed, all future hoisting of water, rock or ore will be done through it, instead of the old shaft and the Crown Point as heretofore.

Ophir.—The daily yield of ore is about 80 tons. The yield of bullion for the present month is several thousand dollars ahead of what it was at the same date in January, showing a steady iucrease in the milling valne. The ore stopes from the 1900 down to the 2000 levels are yielding rich ores. The bullion yield for January was in round numbers $191,000.

Alta.—Sinking a large, double-compartment joint shaft or winze below the 1550 level on the dividing line between the Alta and the Benton, has been commenced, and is making good headway.

Julia Con.—The breakage of the pump-bob has again delayed the drainiug of the water from the 2000 level. The south branch of the Sutro Tunnel, which passes a distance of 20 feet east of the shaft, nine feet below the 1600 station, is rapidly nearing the main shaft. A drift has beeu started east from the shaft to connect with it.

Bullion.—The north drift on the 2400 level is making excellent progress, the face in a soft, lively character of vein matter, showing streaks of fine looking quartz giving low assays, along with a slight seepage of water.

Lady Bryan.—During the first part of the week a fine vein of handsome looking quartz was struck in the bottom of the main shaft while sinking.

Crown Point.—The air connection with the joiut pump shaft was completed on Saturday morning last. This thoroughly ventilates the mine down to that depth.

Consolidated Imperial.—The recent counection of the Yellow Jacket shaft with the 2200 level, which corresponds with the 2400 level of the Imperial, has already greatly benefited the air circulation of the mine.

Belcher.—The north drift on the 2560 level has connected with the south drift from the Crown Point on the 2500 level, affording a splendid circulation of good air and greatly facilitating the work in that portion of the miue.

North Consolidated Virginia.—The big shaft 26½ feet in leugth and 22 inches in diameter, arrived yesterday, and is being placed in position ready for service.

Savage.—The east crosscut, on the 2100 level, has been steadily advanced during the week and is now in 371 feet.

Sutro Tunnel.—The south lateral branch will connect with the Julia shaft in the 20-foot drift the comiug week, a very important connection, giving not only a much needed air circulation, but an outlet for the water which is bulldosing the lower levels of the Julia. No definite or satisfactory understanding has been as yet arrived at between the main Comstock mining companies and Sutro, consequeutly the big tunnel is not made available just yet for hot water drainage.

Leviathan.—Twenty-two feet has been added to the length of the main north lateral drift on the 730 level. The face of the drift is in clay, quartz and porphyry, of a very promising character.

Best & Belcher.—Sinking the Osbiston shaft is making good progress, taking into consideration the strong flow of water. The joint east drift, on the 1700 level, is now in 486 feet.

Trojan.—The south drift from the west drift on the second etation level is in 45 feet, the face in quartz and porphyry, assaying from $10 to $15 per ton.

Utah.—The new hoisting engines are ready to start up. The standing pumps are placed in position ready for service in the main incline.

Hale & Norcross.—Siuking the winze to conuect the 2100 and 2000 levels is making good progress.

Mexican.—The north drift on the 2000 level is steadily advancing, the face in hard, black porphyry. It is now in 380 feet. The joint Union Con. winze below the 1600 level is now down 221 feet.

Silver Hill.—The east crosscut on the 1100 level is steadily advancing, the face in dry, hard porphyry showing streaks of clay.

Caledonia.—Sinking the double perpendicular winze below the 1600 level is going vigorously forward, the bottom in rock that blasts out well.

Justice.—The Pappoose mill is kept steadily running on reserve of ore from the mine.

Union Con.—Sinking the joint Mexican below the 1600 level is making the best of headway considering the extreme hard character of the rock penetrated.

Ward.—The erectiou of the new hoisting machinery is making the best of progress.

Overman.—The north drift on the 1600 level is making good progress; the face still in quartz and vein matter.

Gould & Curry.—Sinking the Osbiston shaft is making good progress considering the trouble caused by the strong flow of water. Repairing the main shaft is making good headway.

Chollar-Combination Shaft.—Sinking the main shaft below the 2250 level is making steady progress. The flow of water at the bottom is still quite strong. The new air compressor will soon be ready to start up.

EUREKA DISTRICT.

Mining Notes.—*Sentinel*, Feb. 8: In our weekly rounds on Ruby Hill, we droppsd into the Eureka Consolidated mines on Tuesday last, where we found everything moving along in the accustomed manner. There is some prospecting work being done on the fifth level, where they have some ors. On ths ssventh and eighth levels, and more particularly ths latter, thers are immense bodies of high grade ore, in which the black metal predominates. It will require a long time to exhaust the ore between thess two levels, which as yet sesms hardly to have been touched. The ors on the eighth level is the richest that has been found in the mine, and, we think, will prove to hs the largest body yet discovered. However, there is but little known of the extent of the ore bodies in this company's mines, as not one-half of their ground has been prospected, and the probabilities are, that in two years hence the property will be much more valuable than it is to-day. One fact has already been proven, that as depth is attained in this mine the ore becomes richer in gold. At the present time one-half of tbe yield from the furnaces is gold. A new tunnel, to be called the Morgan, is about to be started on the west side of Prospect mountain, immediately between the Charter and Prospect mountain tunnels, and running parallel with them. It will cut the Mary Anu, Ozark, Elizabeth, Lady Hull, Erie and other prominent and valuable mines in the mountain. The Phenix is working a force of 30 men. Incline 140 feet. The Jackson continuee to send forth its full quota of ore. Capt. Adam's Silver Lick mine is showing up splendidly. The Mountain Boy, is being worked on a lease by some Frenchmen. Reported doing well. Zinc ore is being taken from the Lizette tunnel. It comes from the old workings of the Richmond minc.

PARADISE DISTRICT.

Credit Mobilier.—*Silver State*, Feb. 1: This mine has been bonded by its owner, A. M. Sadorus, to a Sacramento company. It is situated near R. H. Scott's ranch, in the range of mountains which divide Paradise and Eden valleys. It has been prospected by its discoverer and owner by a shaft to a depth of 60 or 70 feet, and carries the richest gold bearing quartz of auy mine yet found in this part of the country.

Paradise Company.—No dividends as yet. New property, only five months since its discovery; has developed in a most remarkable manner considering the short time the company has been at work upon it. Over $30,000 have already been expended in opening the miue, with, as before mentioned, very remarkable results, for the mine is already producing from 10 to 15 tons of ore per day that assays from $200 to $300 per ton, and thie out-put of ore comes from the drifts being run without any stoping being done. The company is about starting the Rye Patch custom mill, and will not build one of its own until next summer. That this mine will soon be on the dividend list, there is not a question of doubt. There is very little stock for sale, and that finds a ready market at from $2.00 to $2.50 per share.

Bullion.—The Bullion mine is developing finely. The ledge is said to be 20 feet wide, and the ore hody the largest and richest yet found in the district. A part of the Bullion mine has been bonded by Capt. Rawlings of Virginia, who has a force of men employed prospecting it.

REESE RIVER DISTRICT.

Western Nye.—*Reveille*, Feb. 8: The Alexander mill ie now running again with renewed vigor, all necessary repairs having been made. They will ship the usual amount of bullion tomorrow. A new ore dump and railroad track ie being erected near the entrance to the eouth tunnel. The mine continuee to yield large quantities of rich ore, with no new developments to report. The stock recently ran down from $11 to $2, without any apparent cause, as the company's affairs are in good shape, and producing coneiderable bullion, and with their new mill an increase of bullion ehipments may be expected. Within a period of four daye the stock advanced to $6½, the latest quotations received. The furnace at Downeyville etarted up on 25th ult., but the jacket sprung a leak and had to be shut down for repairs; however, it started up again on the 1st. The mines are looking about as well as at any time heretofore. Ou Tuesday morning they shipped several tons of bullion. A ledge has been discovered, three miles from Dowueyville, the croppings of which assay $120.

Manhattan.—During the 24 days that the mill was run in the month of January there was reduced 490½ tons of ore, the assay value of which is $80,959.60; of this amount $21,288.84 was from custom ores; $5,517.27 from tribute mines and $54,333.50 from the Frost and Curtie shafts.

TRINITY DISTRICT.

Numa Co.—*Silver State*, Feb. 8: This San Francisco corporation, have a force of miners employed on the Evening Star mine, eight miles west of Oreana. The mine is said to be looking well and yielding considerable rich ors. The Eveniug Star was worked extensively in the early days of this county, and produced sufficient ore to run an eight stamp mill steadily until water was encountered in the mine, which caused a suspension of operations, and resulted in the desertion of the district. The mill, which was built by ths Evening Star company, was removed from the district, and for years the place was abandoned. One or two of the old owners worked assessments on the mine every year and obtained a patent for it, and some time since incorporated under the name of the Numa company. A lot of ore from the mine will soon be worked at the Hope mill, and the prospects are so encouraging that the working force on the mine has been increased.

ARIZONA.

Globe District.—*Silver Belt*, Feb. 7: Meek & Anderson are arastring El Capitan ors. Thomas Kirvin, on leased ground, has developed rich ore. Good ore is reported struck in the Peacock claim. Several tons of good ore have been sent from the Reseue mine to the Miami mill. The shaft on the Alice mine is now down 90 feet, and in three feet of carbonats ore. The Metamora company is likely to put hoisting works on that miue. Tbe shaft is now about 150 feet deep. Work is being done on the Elephant claim, north of Black peak. The Miami company has started to crush ore. Fifty tons are in the mill. The Queen mins ehows well-defined walls, and good ore ie in sight. Shaft down 40 feet. On Wednesday last a large body of rich ore wae struck in the Stonewall Jackson. Its estimated value is $1,000 per ton. Machinery passed through thie place last Tuesday for the concentrators now in the course of erection at the Wheatfields. The Mattie West, extension of the Belgium, is prospecting well. Some of the ore has assayed 346 ounces. It belongs to Lieurance Bros. & Co. George Weher, who was prospecting a blind lead, discovered promising ore.

IDAHO.

Silver City Notes.—*Star*, Feb. 4: At the Black Jack mine work is progressing. Considerable is being done in the way of prospecting and putting the mine in shape for work the coming season. Large ehipments of ore are daily heing made to the mill. The ledge is looking unusually well, and is yielding the regular supply of rich ore. The mill is running to its full capacity, with prospect of the necessary water supply for the winter months. The mine on Florida mountain is turning out first-class rock. The ledge is eight feet wide, and the rock now being crushed at the Leonard mill will yield somewhere in the vicinity of $70 to the ton. The Potosi is looking well. The mine has been producing a good supply of ore during the past few weeks, averaging nearly $50 to the ton. There are some 20 men employed. The Morning Star mine has been put in condition foi active operations, and the work of taking out rock will commence in a few days. The Mahogany mine and works have been sold at Sheriff's sale for $10,000.

News in Brief.

The thermometer at Salt Lake has touched zero.

California lions kill many pigs in Butte county.

Two high Turkish officials have proved incorruptible.

Stockton hae admitted colored pupils to the white schools.

One hundred and one deaths occurred in this city last week.

Fresno county has a 12-year-old boy who stands six feet two inches.

Several mines on the Comstock lode have been attached by creditors.

A man was lately killed in Philadelphia by the explosion of a beer barrel.

An embargo has been laid on the importation of American cattle into Canada.

At Drytown a lady named Mrs. Spooner committed suicide by hanging.

A fatal horse disease prevails about Newberg, Yamhill county, Oregon.

Passenger travel over the Central Pacific railroad ie very ligbt at present.

Passanante, who attempted to kill the King of Italy, has been pronounced sane.

R. L. Ryan fell down the shaft of the Bodie mine on the 6th inst. and was killed.

Queen Victoria is about to become a great-grandmother, and not yet 60 years old.

Napa City is to have a pottery which will be in operation in the course of a few weeks.

A Montana snow-slide lately swept away an ore-shed, killing three men and six horses.

The St. Gotbard tunnel is now 13,481 feet long, being the longest tunnel in the world.

The Tulare foothille are covered with green grass, but it is not yet long enough for feed.

The Sandwich Islands are likely to become a place of refuge for Chinamen leaving California.

The city of Memphis has suppressed her charter as a corporation, to avoid paying her debts.

There is estimated to be 4,500,000 barrele of petroleum in the tanks in the oil region of Pennsylvania.

No more silver five-cent pieces will probably be coined, and their place ie to be filled by nickles.

There are at Cheyenne 3,000,000 pounds of boilers and machinery awaiting shipment to the Black Hills.

A new "Municipal Reform" party has been started in San Francisco. It is non-partisan and purely local.

The value of real estate and improvements in Napa county is $6,818,390, and of personal property $1,297,951.

Revised returns of the production of wine in Napa county in 1878, show that 2,100,000 gallons were made.

About 20,000 buildings, costing over $280,000,000, have been erected in New York during ths past 11 years.

Dakota has an army of immigration agents working Iowa and other States in the interest of that Territory.

The Southern Pacific railroad employs in Arizona 1,200 laborers—1,000 Chinamen and 200 white men.

In view of the late Supreme Court polygamy decision, the Mormons have entered a protest and taken more wives.

Measures for preventiug the spread of the plagus have becn, or are about to be, taken by every nation in Europe.

The uames of a number of naturalized citizens have been stricken from the great rsgister on the ground of fraud.

The buds of almond and cherry trees in the vicinity of Marysville, California, ars nearly ready to burst into blossom.

Three children in Sutter county came nsar being fatally poisoned by chewing the inside bark of the black locust tree.

Durino January the grain shipmsnt from the Salinas depot of the Southern Pacific railroad amounted to 631,284 pounds.

A lady named Davenport was thrown from a buggy at Visalia and received injuries from which she died the same day.

A party of Tehama bear hunters killed three grizzleys last week. The largest weighed between 800 and 900 pounds.

Orange, Los Angeles county has been experiencing the visite of horse thieves. Five were stolen on Friday night last.

According to judicial investigations recently had in San Francisco, the price of Chinese women ranges here from $100 to $700.

The last survivor of the Lewis and Clarke expedition, a colored man, aged nearly 90 years, was frozen to death lately iu Virginia.

Coyotes are killing a large number of eheep in Tehama county. The withdrawal of the scalp bounty is pronounced an injustice.

Miss Tortillot lately walked 48 hours in Stocktou without food, drink or rest. What useful things she is able to do is not stated.

Michael Hall, a stout young Irisbman, on a wager, drank a quart of whisky at one draft in Sutro, Nevada, last week, fell down in a stupor, was taken to his lodgings and dicd.

A man lately fell into the water in the lower levels of one of the Comstock mines and was scalded to death. This water was heated to a fatal temperature wholly by natural causes.

The amount of counterfeit coin in circulation in the United States is said to be $2,000,000, besides the great number of genuine pieces made fraudulent by the removal of part of the metal.

While the Irish will celebrate St. Patrick's day in this city, a uumber of organizations will decline to march in the procession, preferring to observe the anniversary in some less ostentatious manner.

John Timmerman was found dead in the road ten miles from Wickenburg, Arizona, recently. He was ehot in the side, and is supposed to have been murdered for his money, as he had some $700 on his person.

A letter from Dublin states that while in Ireland Gen. Grant wae constantly ehadowed by a Dublin detective, who expected to discover evidence that Gen. Grant was the Fenian headceuter of the United States.

Our Eastern Agency.

We have established a special Eastern Agency for the Press at No. 38 University Place, New York City, with MR. JOHN MICHELS. He will correspond for our columns, and also receive subscriptions, advertisements, etc., for the accommodation of our Eastern friends.

Fresh attractions are coustantly added to Woodward's Gardens, among which is Prof. Gruber's great educator, the Zoographicon. Each department increases daily, and the Pavilion performances are more popular than ever. All new novelties find a place at this wonderful resort. Prices remain as usual.

Artesian Wells Wanted.—Parties who are prepared to contract for boring artesian wells are invited to send terms to Edward Frisbie, proprietor of the Reading Ranch, Anderson, Shasta County, Cal.

Settlers and others wishing good farming lands for sure crops, are referred to Mr. Edward Frisbie, of Anderson, Shasta County, Cal., who has some 15,000 acres for sale in the Upper Sacramento valley. His advertisement appears from time to time in this paper.

Examine the accelcrative endowment plan, as originated by the Mutual Benefit Life Insurance Co., of Newark, New Jersey. Assets, $30,533,429.94. Lewis C. Grover, President; L. Spencer Coble, Vice-President; Benjamin C. Miller, Treasurer; Edward A. Strong, Secretary; Bloomfield J. Miller, Actuary. DEWEY & CO.—*Gentlemen:*—Having received my Letters Patent for improvement in vehicle wheels, I consider it a duty I owe your firm to tender my sincere thanks for the interest and pains you have taken in the prosecution of the case. I shall cheerfully recommend your firm to such as may need your services. I remain yours,

Very Respectfully, WM. THUNEN.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

Cherokee Flat Blue Gravel Company.—

Location of principal place of business, San Francisco. Location of works, Cherokee Flat, Butte County, California.

NOTICE.—There is delinquent upon the following described stock, on account of assessment (No. 40), levied on the 20th day of December, 1878, the several amounts set opposite the names of the respective shareholders, as follows:

	No. Certificate.	No. Shares.	Amt.
A. Cassell	17	4608	$230 40
L. Nussbaum	105	50	2 50
E. I Pfeiffer	106	430	21 50

And in accordance with law, and an order of the Board of Directors, made on the 20th day of December, 1878, so many shares of each parcel of such stock as may be necessary, will be sold at public auction, at the office of the company, on Tuesday, the 18th day of February, 1879, at the hour of two o'clock, P. M., of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of the sale.

R. N. VAN BRUNT, Secretary.

Office, No. 318 Pine Street, Room 6.

Griffith Consolidated Mill and Mining Com-

pany.—Location of principal place of business, San Francisco, California. Location of works, Diamond Springs Mining District, El Dorado County, California.

Notice is hereby given, that at a meeting of the Board of Trustees, held on the 21st day of January, 1879 an assessment (No. 1) of twenty cents (20c) per share was levied upon the Capital Stock of the Corporation, payable immediately to the Secretary, at the Office of the Company, Room 48, 330 Pine Street, San Francisco, California.

Any Stock upon which this Assessment shall remain unpaid on the 26th day of February, 1879, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on Wednesday, March 26th, 1879, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Trustees.

GEO. M. CONDEE, Sec'y.

Office, Room 48, 330 Pine Street, San Francisco, California.

Office Wide Awake Prospecting and Min-

ing Company.—No. 232 Sutter Street, San Francisco, Cal., February 1st, 1879. Location of works, Picket-Post, Pinal County, Arizona.

Notice is hereby given that at a meeting of the Board of Directors, held on the first day of February, 1879, an assessment (No. 6) of four cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin to the Secretary, at the office of the Company, Room 2, No. 232 Sutter Street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the first day of March, 1879, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Saturday, the fifth day of April, 1879, to pay the delinquent assessment, together with the cost of advertising and the expenses of sale. By order of the Board of Directors. C. HILDEBRANDT, Secretary.

Summit Mining Company.—Location of

principal place of business, San Francisco, California. Location of works, Mineral Point Mining District, Plumas County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the fourth day of February, A. D., 1879, an assessment (No. 7) of five cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the Company, 318 Pine street, San Francisco.

Any stock upon which this assessment shall remain unpaid on the eleventh (11th) day of March, A. D., 1879, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on the eighth day of April, A. D., 1879, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

R. N. VAN BRUNT, Secretary.

Prompt Attention to Business.

AURORA, Nev., Dec. 7th, 1878.

MESSRS. DEWEY & CO., S. F.—*Dear Sirs:*—I acknowledge the receipt of my patent per express this morning, and am obliged for same. I do not know what to say to you regarding your prompt attention to business, but will say to my friends what I cannot say to you. Many thanks is what you will get from Yours truly, C. W. LANE.

Fine Engraving.

The Engraving Bureau belonging to the office of this journal is prepared to design and engrave all kinds of WOOD CUTS for illustrating newspapers, books, catalogues, cards, circulars, advertisements, labels, badges, seals, etc., in the best style of the art. Our portraits and illustrations of machinery, buildings and landscapes, are superior. Good engravings can be made from paintings, lithographs, steel and copper plate prints, photographs, models, patent office or other drawings. We have a photographic department and the best of machinery for producing accurate and perfect work at the lowest prices. Original maps, charts, and diagrams are made by our NEW PHOTO-RELIEF PROCESS at greatly reduced rates. By the same process copies can be cheaply and quickly produced of printed cuts, in *fac simile*, or they can be enlarged or reduced with equal facility.

Any hand writing in perfectly black ink on clear white paper for manuscript letters or circulars, will be accurately reproduced in metal plates suitable for common printing. Also, *fac simile* signatures, monograms, sheet music, etc. We excel in trade cuts and matched plates for combination color printing. With a large business, long established, and every facility for improvement, we can guarantee more than ordinary satisfaction to all of our patrons. All interested are invited to send for or call and see specimens and obtain prices.

Orders for electrotypes, stereotypes, steel and copper plates, lithographing, stamps and seal presses executed at low rates.

ARITHMETIC MADE EASY

BY ROPP'S

Easy Calculator.

This valuable work is used by thousands of farmers, mechanics and business men, and is highly recommended for its practical utility and convenience.

It embodies an entirely new system of calculation, by which a vast amount of figures and mental labor—required by the ordinary methods—and fractions with their complexities, are absolutely avoided.

It is so simple and easily comprehended that even the most illiterate is enabled, in a few minutes, to reckon with absolute accuracy and speed; while its original and rapid methods, benefit and delight the most scholarly.

It shows at a glance the accurate value of wheat, corn, rye, oats, barley, cattle, hogs, hay, coal, lumber and merchandise, from one pound to a car load, and for any price the market is likely to reach.

It gives the interest, simple and compound, on any sum, or any time, at six, seven, eight, and ten per cent.; the exact measurement of boards, scantlings, timbers, saw logs, cisterns, tanks, wells, granaries, bins, wagon beds, corn cribs, etc., the wages at various rates, for hours, days, weeks and months; besides numerous other important methods, rules and tables.

It is printed on fine tinted paper, is well and elegantly found in pocket-book shape, and accompanied by a silicate slate, pocket for papers, and memorandum, which can be replenished in the two latter styles.

It answers the purpose of a pocket book and diary, and costs no more, although it was gotten up at great expense and labor, and is unquestionably one of the most useful publications ever issued from the press.

Price, bound in Fine English Cloth, $1.00.

Sent direct from the Eastern publisher, postpaid, on receipt of price, by P. O. order, registered letter or receipted by express. Address

SAVE YOUR GOLD

And Also SAVE YOUR QUICKSILVER.

The above Washer and Amalgamator with new patent Wire Bridge Quicksilver Boxes attached, can be worked wet or dry, either by hand, steam, horse or water power, and is easily taken apart and packed. For washing Pulp, Earth, Gravel, Mill Tailings or Black Sand, it is without a rival.

Has been Thoroughly Tested and given Complete Satisfaction.

The entire Lining, Hanging Plates, Riffles and Boxes Amalgamated

IS GUARANTEED TO SAVE THE FINEST OR FLOAT GOLD.

Capacity, 30 to 60 tons per day, according to size. For further particulars apply to

J. MORIZIO, Gen'l Agt.,
Room 24, Safe Deposit Building, Corner Montgomery and California Streets, SAN FRANCISCO.

Ingersoll Rock Drills.

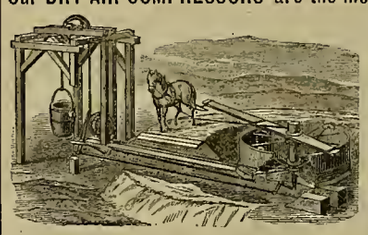
In use in the largest and best Mines of the Coast.

HAS AUTOMATIC FEED.

Has less Repairs.

Is Lighter and more Easily Adjusted than any other Drill.

Our DRY AIR COMPRESSORS are the most Economical Compressors in the Market.



MINERS' HORSE-POWER.

This Power is especially adapted to working mines, hoisting coal or building material, etc. It will do the work of a Steam Engine with one-tenth the expense. One Horse can easily hoist over 1,000 pounds at a depth of 500 feet.

The Power is mainly built of wrought iron, and cannot be affected by exposure. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

The Large Circulation of the MINING AND SCIENTIFIC PRESS extends throughout the mining districts of California, Nevada, Utah, Colorado, Arizona, Idaho, Montana-British Columbia, and to other parts of North and South America. Established in 1860, it has long been the leading Mining Journal of the continent, its varied and reliable contents giving it a character popular with both its reading and advertising patrons.

This paper is printed with Ink furnished by Chas. Eneu Johnson & Co., 509 South 10th St., Philadelphia & 59 Gold St., N. Y.

Paul's Dry Amalgamating BARREL PROCESS.

This is the most perfect of all systems for amalgamating the precious metals—more especially gold, for which it is absolutely perfect, the per cent. of metal obtainable being only governed by the fineness of reduction of ore. It will gather the flour gold with the same readiness as the coarse. The machinery and operation is simple and practical—not requiring skilled labor. Its efficiency is verified by mills in practical operation. I will contract for mills of 10, 20, or 50-ton capacity per 24 hours. Pamphlets, explaining the process more fully, forwarded on receipt of address. For further particulars apply to

ALMARIN B. PAUL,

A New Safety Powder.

The Safety Powder Company is an incorporation recently organized in this city for the manufacture of new explosives for mining and engineering purposes, which are claimed to possess certain characteristics, indicated by its name, in a greater degree than has been considered possible in high explosives. This result is reached by so making the powder that it will not explode except under *three* conditions, which conditions are those which ensure the greatest safety, and are also those under which powder is used. For instance, other powders are made, which are not supposed to explode, except under the conditions of heat and percussion both applied at the same instant, but will explode in the open air when these conditions are fulfilled. The powder in question is so made as to explode only by heat, percussion and confinement, which three conditions must be fulfilled before its explosive qualities will appear. That is to say, it must be fired by a proper fuse and cap and be tamped down, otherwise no explosion will occur. If therefore a cap were fired in the powder in the usual way, provided the cartridge was not tamped and powder closely confined, no explosion would follow.

This statement may appear somewhat strange to those accustomed to use high explosives, but as far as a few simple experiments will prove, is borne out by the facts. We visited the works of the company on the corner of Greenwich and Octavia one day last week, and witnessed a series of experiments with the powder, some account of which may be of interest to our mining friends.

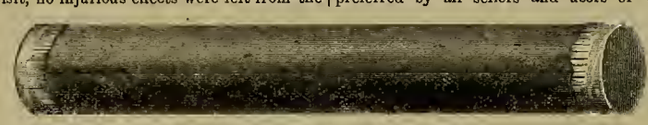
In the first place it may be stated that this compound contains no nitro-glycerine whatever, an invariable explosive chemical ingredient being one of the salts of potash, to which are added other substances, some of which are necessary to the evolution of the explosive force, whilst others reduce it to any degree required for safe handling, and cure any natural tendency to decompose or explode spontaneously. By this means the compound is rendered safe to handle, while its practical explosive qualities under suitable conditions, are in no degree impaired, but generally augmented. Any of several ingredients may be mixed with the explosive compound, according to nature and quality of compound, and the time when and the circumstances under which the explosive material is to be used.

Ample facilities were given us by the manufacturers of the powder, in testing its properties as far as was possible by a few experiments. We took a good substantial sample from the common stock, so as to try the same article in several ways. The first thing to do was to try its explosive force, and as this could only be tested comparatively, samples of Giant, Hercules and Vulcan were first fired, and then the Safety powder.

These samples were all fired with Field's platinum electric exploder and triple Giant caps. They have arranged at the works a simple testing machine, by means of which, when the powder is exploded a weight is thrown up on guides, and the bight automatically registered. A plunger or piston on this weight rests on the charge in the metal block, and as the charge explodes, the weight is thrown up. The charges were therefore "only piston tamped." Each of the samples weighed 100 grains. The first one tried, lifted the 265-pound weight 24½ inches; the second raised it 16¼ inches; the third 16 inches; and the Safety powder under same conditions of piston tamping, raised it 19 inches. When, however, the Safety powder was strongly tamped in the hole, and the piston again rested on the tamped charge, the explosion raised the weight up 76½ inches vertically. This showed its explosive effect was only fully realized when the conditions under which it was to work were properly fulfilled.

To test whether this powder would explode when not confined, we made up a quarter of a pound in a strong cartridge, solidly tamped with a triple Giant powder cap and electric exploder firmly imbedded in the powder. This cartridge we prepared ourselves from the sample originally made, taking care to pack the powder firmly. This was placed on the sand in the lot and the exploder discharged by electricity in the same manner as a Giant powder cartridge is exploded. The effect was somewhat surprising. The exploder fired the cap which exploded with its usual force and burst the cartridge open, but the powder in the cartridge did not explode. One end of the cartridge was found some distance off with probably an ounce of powder still packed in it. Part of this remaining powder we burnt in the open air, and part was placed in the tester after tamping it, where it exploded properly.

We next tried some of the powder on an iron surface by striking and rubbing it with a hammer, but with no results. Part of the sample was then placed on a tube closed at one end. Common gunpowder made into a paste by the addition of oleeginous metter was put on on top of this end the powder lighted. It burned fiercely but slowly, heating the tube to bright redness as the fire entered the tube. On reaching the Safety powder, that in turn burned but no explosion followed, showing that at a red heat it would burn but not explode. It should be stated that although considerable of this powder was burned and exploded during our visit, no injurious effects were felt from the fumes, which are stated to be entirely harmless.



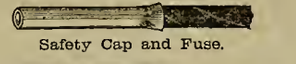
SAFETY POWDER CARTRIDGE.

The mode of explosion of this powder is different from that of any other high-grade explosive now in use. When tamped lightly it develops like powders, and gives off peculiar products of combustion; but strongly tamped it develops a very large measure of power, and is said to give off very different products of combustion. The powder is therefore specially fitted for strong tamping and will do very good work.

This same powder is made to do duty in a safety cap manufactured by the same company. To try the force of these caps a small tester, similar to that used for trying the powder, was used.

The first triple Giant cap raised the five and one-half pound weight six and one-half inches; the second, seven inches; and the third, six and one-fourth inches. The first safety cap raised the same weight 11 inches; the second, 19 inches; and the third, 18 inches. These were fired with the piston of the weight resting on them. Then the safety caps were again fired, but first tamped. The first under these conditions raised the weight 44½ inches; the second, poorly tamped, eight and one-half inches; and the third, well tamped, 43¼ inches.

Safety Cap and Fuse.



Electric Cap.

The class of exploders commonly employed to ignite that large class of powders like the Giant, Hercules, Vulcan, and other powders, which require a powerful concussion to produce an explosive ignition, consist usually of a cap filled with a powerful fulminate, this cap being imbedded in the cartridge and having a fuse in it. These caps have to contain so much of the fulminate that they are in themselves very dangerous on account of the ease with which they may be exploded.

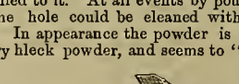
The exploders made by this company consist in filling a tube with the peculiar powder described, which requires to be ignited under pressure in order to explode. A wad of an ignitible or explosive material is used to retain this powder in its place in the tube and renders the ignition of the charge certain, communicating the fire from the fuse to the powder. When the fuse is pushed into the tube, said tube is pinched firmly at its upper edge so as to compress the fuse end hold it tight. When this is done the conditions are fulfilled which render the exploder effective. An engraving on this page shows one of these exploders prepared for its work. When strongly pinched on this fuse they will explode with much greater force than the strongest percussion caps. We saw one of these exploders violently pounded with a hammer on an iron surface without its exploding; and also saw it lighted and burned in a red-hot tube without any explosive effect.

An additional feature in connection with the exploders is a fuse lighter, a novel invention, which will be used in place of snuffs or squibs. It consists in attaching to the end of the fuse a small charge of highly combustible material in a combustible envelope which serves to fire it, while the shell, which holds and fastens it on the end of the fuse, is so formed as to direct the blaze with blow-pipe energy against the end of the fuse and insures ignition.

Altogether the foregoing facts developed by our examination, lead us to the conclusion that under a series of patents already granted and others recently applied for, this company are producing for civil engineering and mining works some very novel and valuable products.

The safety cap, safe to handle and even to set on fire if not confined, with far more power than any percussion caps in use—will certainly be preferred by all sellers and users of Giant, Hercules, Vulcan or other detonating powders.

The fuse lighter, fastening on the end of the fuse, and lighting it without fail, is so much more convenient and certain than "snuff's" that we should think once known miners would be sure to use them. An engraving shown herewith will give an idea of the use of this fuse lighter. Judging from what we saw the other day, we should think that in using Safety powder and caps no hole need ever be lost. The cap can evidently be pulled or dug out with perfect security, and the powder taken out by any thing that would not give it harder friction than we saw applied to it. At all events by pouring in water the hole could be cleaned with an iron spoon. In appearance the powder is dry like ordinary bleck powder, and seems to "set" soon after being put up. In this State, of course, it is not liable to freeze.



Fuse Lighter and Fuse.

ROWELL'S AMERICAN NEWSPAPER DIRECTORY. The January issue of this quarterly, containing some 550 pages, is on our table. Aside from its intrinsic merits, the book is a handsome one, doing credit alike to the printer, the binder and the compiler. As this work contains an accurate list of all the newspapers and periodicals published in the United States, Territories included, the Dominion of Canada and Newfoundland, it ought to be one of general interest and utility. It should prove especially serviceable to the advertising community, showing as it does the circulation of every publication on its list, thereby indicating the value of each as an advertising medium. It also contains much valuable information in regard to the leading cities and towns in the above countries, this gazetteer feature being new with the present number. The work is issued quarterly at the rate of $5 per year to subscribers, and has now a large circulation.

A MISPLACED switch in the yards of the Indianapolis, Cincinnati and Lafayette railroad threw an incoming locomotive into a tank-car loaded with oil, which took fire and burned a number of cars. Loss, $7,000.

THE recent report of cattle men being murdered in Nebraska by Indians has been confirmed.

Should Earn a Little More and Spend a Little Less.

To the practice of the economy indicated above, our people must bring themselves before they can reasonably hope to experience any marked or permanent improvement in their physical condition. We know that this sort of thing has been preached a good deal, and may be looked upon by the classes for whom it is more especially intended, as being a little stale and monotonous. Besides, the majority of these people are apt to think that they really do earn as much and spend as little as is consistent with their health, comfort and social position. And so they do, if they are going to be particular as to the condition on which they accept employment and the kind of labor they perform—always insisting upon the shortest hours and the highest wages; are going to indulge in useless luxuries, and cherish a variety of artificial appetites; smoke, drink, take time for balls, billiards and horseraces, frequent the theaters, go weekly on picnics, pleasure excursions, etc. No class of laborers, or persons who work for day wages, or on small salaries, can pursue a course like this, and expect to thrive. Take, for example, the young man who is addicted to going to balls or dances. As these amusements are carried on at night, he is necessarily unfitted for work the next day, which, with the time lost in preparing for them, causes him on an average a loss of two full days. Then the expense consumes the earnings of two or three days, to say nothing of the extra fine clothes these balls require, the injury to health they occasion, etc., making a serious total of mischief worked through indulgence in what is generally accounted a harmless recreation.

While it is probable that we shall have a tolerably good year for farming and mining, not much improvement need be looked for in our mechanical and manufacturing industries. These will remain depressed; building will be dull and labor of most kinds be in limited demand and possibly at reduced prices. The Chinese still remain with us, a considerable immigration from the East will bring fresh supplies upon the labor market, while increased transportation facilities force us into sharp competition with manufacturers abroad. The industrial outlook is such, therefore, as admonishes the masses wanting work to the practice of prudence and economy. They should at once begin to husband their resources and reduce expenses to a minimum. Employment of almost any kind should be accepted even though the wages be moderate, and those having situations should retain them without being particular about minor conditions. Money on hand should be hoarded. It is no good time this, for people of small means to be gambling in stocks or embarking in other hazardous speculations. Let them hold on to what they have and try and add a little thereto, retrenching expenses wherever possible. The good old days of the slugs and ounces have passed away. The era of the *nickel* is upon us, to be followed, perhaps, by that of the old-fashioned red cent, a coin of small purchasing power but with some of us of blessed memory. Though they had in the South aforetime no coin less than the picayune, the mass of laborers there were not thrifty. Having lived in California to see this day of small things let us wisely conform to its requirements, bearing in mind that a little more earned and a little less spent is a policy that will secure to us now a larger share of the comforts of life than were common in the flush times of the past.

ROBERT T. BURTON is on trial at Salt Lake for the murder of Mrs Bowman in 1862. It is charged that after the surrender of a party of Morrisites to Mormons in that year, he shot and killed Morris and two women.

THE Constitutional Convention of this State, and the Legislature of Nevada, have telegraphed resolutions to President Hayes, urging him to sign the Anti-Chinese bill.

JAPAN is now manufacturing boots for the United States from leather brought from American ports.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

Siskiyou Notes.

Editors Press:—A perusal of the interesting "Notes on Trinity County," recently published in your paper, has induced the writer to send you the following notes on Siskiyou county. This county presents an inviting field for hotb capital and lahor. Her mountains are rich in gravel deposits and quartz veins, bearing gold in paying quantities. From these snow-clad mountains numerous streams of ever-living water wind tbeir way into the beautiful valleys below, of which Scott and Sbasta valleys are the most beautiful, fertile and productive, yielding never failing and abundant crops of wheat, oats, barley, timothy, alfalfa and every variety of vegetables. Her towns and villages are conveniently located at the hase of the mountains, so as to command the trade of the farming and mining sections, and in a measure unite tbese interests.

It is claimed by some that our

River and Placer Mines

Are nearly worked out. Tbis is a mistake. Fifteen years ago the same cry was raised "that the mines are worked out," and yet we have more extensive and gigantic mining enterprises here now tban ever heretofore. On the South fork of Scott river Denny, Parker & Co. have, at a cost of $30,000, and several years of patient labor, opened a river claim that is paying $1,200 to tbe sluice length with pick and shovel. And then the Bennet & Miller claim on Salmon river, Pacific claim on tbe Klamath river, "Lucky" Baldwin claim on Yreka creek, and other mining operations demonstrate that we have many rich and extensive fields for mining operations, which require only tbe necessary energy, capital and lahor to make them remunerative.

A Great Gravel Deposit

Extends from Trinity county, in a northerly direction, through this county into Oregon, and where broken by streams, has been very rich. We bave good facilities for obtaining water for miuing purposes, and the mountains usually retain the snow and keep the streams up to ahout the first of July. The average rainfall is ahout 25 inches. Timber for lumher and mining purposes is plentiful, and easy of access for all the mining regions. Produce is cheap, flour heing only $2.50 per 100 pounds. Being connected hy good wagon roads with Reading, the present nortbern terminus of tbe C. & O. R. R., freight can be hrought here from San Francisco at three cents per pound. Lahor is cheaper than in most other mining localities. The experience of working

Quartz Mines

Has shown that rock can he extracted and reduced at a cost of $4 to $5 per ton. Of late years more attentiou has heen given to the development and working of quartz mines. The most notable mines are the Black Bear, Klamath, Evening Star, Northern Star and Star of the West on Salmon river, which now employ ahout 500 men, and are well paying mines. Tbe Johuson mine, at Oro Fino, which is now opened to a depth of 300 feet or more, the rock of which has thus far averaged $30 per ton. The Empire, Tonkin's Con.; Blind Lode, Blue Jay, Elephant, Horsler, Hartstrand, Kingery and Root minos are hcing opened and give most flattering prospects. These last six mines are located on the Frcnch Creek lode, whicb can he traced for a distance of four miles.

Mr. H. C. Cory,

A resident of this place and a most enterprisiug gentleman, owns the Blue Jay and Elepbant, which are eacb 1,500 feet in length. He has expended considerahle money in opening these mines, and is deserving of great credit for the energy and pluck he has shown in his efforts to make this a successful mining enterprise. He is now down on the ledge ahout 150 feet, wbere the vein averages ahout four feet in thickness, and carries gold iu paying quantity as far as prospected.

The ore from his mines has paid, by milling process, from $10 to $60 per ton, and the ore body improves in quantity and quality with deptb. Assays of average rock from these mines have shown $65.84 per ton. The snecessful opening and working of these mines will he of great henefit to our people, and they should give all possible encouragement to these mine owners. With few exceptions the quartz veins extend in a course nearly north and south and parallel with the mountain ridges. All the veins thus far discovered bave heen found where streams of water have cut through them. These streams are usually chosen for mill sites, as they afford ample water and timher for mill and mining purposes. Our mines are mostly opened in these outside counties with

Home Capital,

And sometimes by inexperienced men; hence the many discouraging failures, which are alike detrimental to the development, growth and prosperity of the country and mining enterprise, as they deter men from engaging in mining operations.

All that our mines need to invite foreign capital and experienced miners to invest in them, is a proper representation. Sbould a few San Francisco mining companies once obtain a footing here, more would very soon be knowu of the mineral wealth of this locality, and a new impetus would he given to the mining interests of Siskiyou. Etna.

Etna, Siskiyou Co., Jan. 25th, 1879.

Progress of Bodie.

Editors Press:—Since last April, when I wrote a series of letters from here to the Press, the population of the district has doubled. Four thousand is a low enough estimate now, with two stage lines and a fast freight line; making additions daily. The Carson route has a strong rival direct from Virginia City—that via. Mason valley, and utilized by John Allman. Early in the season, the Sonora route will be reopened. The Virginia and Truckee railroad is recorded as on the eve of extending a branch this way as far as the foot of the grade at Aurora, via. Mason valley; so that what was a year ago a *terra in cog.*, is destined to he hrought to the doors of San Francisco at a very early day. Bodie is the central attraction for the time, hut it will he singular indeed if Mono county generally does not come to the front as a fresh field of great magnitude in the mining way.

The writer was

Not Surprised

At the excitement created here last July and August. The Standard mine could have anticipated it on a larger scale, had tbe management been disposed to crowd its rich reserves to the front. Lucky for the district tbat this did not take place, else matters would have a gloomy instead of a cheerful outlook at this time. Tbe Bodie claim had little or no development made, and no sooner did the Bruce ledge stick one end out hy the light of the tallow candle, than the work of scooping out begun. By hurrying up heavier machinery, they have got work so advauced that it is possible a new level of importance may he opened before tbe ores overbead are exhausted. I find

More Reserves

Than expected, and am almost convinced that the company will continue its regular dividends until new ore hodies are found. Tbe public at large bave prohably been mislead regarding the real extent of the Bodie mine, the Bruce honanza having overshadowed the Burgess, and especially tbe Gildea. The latter has supplied a great deal of ore that paid well to mill, and is not yet exhausted above tbe 250 level. All three ledges continue below, hut it remains to he seen whether they bold their own every way to the proprosed new level. If they do, Bodie stock will repeat its highest figure and more, too.

The Three Ledges,

Which have rendered the Bodie claim so famous, extend uorth into the Standard, the Burgess shipping ore of a very high grade, wbile the Bruce carries with it all the characteristics of its hest days; in all, practically doubling the value of the originally great Standard property, the main ledge of which constitutes a back-hone that Bodie district could not as yet live without. It has heen one of the very best managed institutions in the history of quartz mining; characterized hy hoth faith and foresight. They are now putting the macbinery in place for sinkiug tbe new Central shaft to a greater depth than any other company possihly can go at present. All the pumping and air-compressing machinery is on the grouud. Tbe new shaft is near 800 feet in depth now, and will he sunk douhle tbat depth if necessary.

Crosscuts

From the 1200 or 1500 level will he quite apt to settle the future of Bodie Bluff. The Bulwer claim is under the same management, and is "proved up," as tbe miners say, to be scarcely second to tbe Standard in importance. A crosscut from the new sbaft of the Standard has found the Ralston ledge in the Bulwer 180 below tbe old levels. With the Homestake and Stonewall ledges carried down to tbe 400 level, including all their well-known richness, and there will he a solid hasis for a sensatiou that will oversbadow the affair of August last. A very few feet of crosscut will decide this matter.

The Want

Of the district at present is another good mill; some such close-working reduction works as the Standard. The Bodie company's mill is unfortunate in not having a regular supply of water. Tbey are still prospecting for it, and the Bulwer ore goes hegging. Tbe Bodie company are still employing the Syudicate mill under contract of last summer.

Other Mines.

Tbe Summit company are developing a hullion-prodncing mine. Con. Pacific recently made a shipment, and is carrying out a general system of development. Tbe Tioga Con. is the Standard north, and is one of tbe interesting features of the district. The Jupiter is supposed to he the south extension of the main Standard mine; is a strong, rich ledge and threatens to make more tban a ripple of excitement some day. The Dudley, still farther south on same line, is a fine showing for a hig mine. As I get around and see for myself, I will endeavor to interest your readers on tbe subject of the Bodie mines for some weeks to come. W.

Bodie, Mono Co., Feb. 5th.

Railroads.

Eastern Capital Seeking Good Investments.

The *Railway Age*, Jan. 9th, says: The distrust that has heen felt by Eastern capital, since tbe panic, in regard to investment in Western railway enterprises—often, it must he admitted, with too good reason—is now rapidly yielding, and while much greater caution will he exercised hereafter in regard to the character of the enterprises and the men iu charge of them, there will he an increasing disposition to invest in tbose that seem to have a sound basis, tho continued growth and development of the West being admitted to ho heyond question.

The changed sentiment is illustrated in the following extract from an interview hy a Kansas newspaper man with the President of the Central Branch Union Pacific road: The *Champion's* representative asked him if the Easteru people of the road were prepared to supply the necessary funds for the prosecution of so gigantic an enterprise. Mr. Pomeroy replied tbat tbey were not only prepared, hut in their anxiety for investment the directors had been compelled to refuse application for stock, and tbat enough money, when necessary, would he subscribed in five minutes' time. Money was so cheap in the East that it was continually seeking Western investment, and the distrust felt a few years ago in Western stocks and honds had given way to an absolute demand, and that money was being taken every day from legitimate Easteru channels and used for speculative investment in Western enterprises. He cited as an instance tbat great stock wonder, the Santa Fe road, which advanced from a drug at 10 cents to an active demand at 85 cents.

The Northern Pacific

By the contract awarded December 28tb, in New York, will be completed to within 25 miles of the Montana line, and 100 miles of the Yellowstone, opening up a section including some of tbe hest agricultural land in the United States.

The Directors awarded the contract for huilding the first 100 miles of the road west of the Missouri river to Walker & Clark. Walker is a resident of Peeksville, and Clark lives in Montana. A great many other contractors were present at the office, and disappointment set very visihly on their countenances. Tbe company will pay the contractors monthly in cash, reserving 15% until the completion of the contract. The cross-ties, railroad iron and fastenings will be furnished by the company, and 100 miles of the road is to be in running order by November 1st, 1879. No attempt will he made at present to bridge tbe Missouri river at Bismarck, but a good ferry will he established, beginning at Heart River Valley, opposite Bismarck. Tbe line, as at present surveyed, runs nearly west to tbe Yellowstone, at the mouth of Glendive's creek, which is about 30 miles helow Powder river.

The country is rolling prairie, said to he well supplied with wood, water and grass. Coal is found at a distance of 25 miles from the Missouri river, and from tbat point west coal veins crop out on nearly every stream crossed.

Some of the Montana papers that declare the N. P. R. R. grant forfeited, stoutly refuse to lend credence to the tclegraph, or to any reports of vitality in the Northern Pacific under any circumstances.

The Bodie Railroad.

Alpine *Chronicle*, Jan. 4: The building of the branch railroad from Mound House to Bodie has heen decided upon. D. O. Mills, President of the company, is now in the East, where he has made satisfactory arrangements for the rails and rolling stock. Tbe work of getting out timhers, etc., will go on this winter, and the grading of the road will he commenced early in the spring. The rails will be shipped this season.

In Arizona.

Arizona Sentinel, Jan. 4: Work was commenced Novemher 18th, but the main force of graders did not arrive until Novemher 20tb and 21st. During tbe week ending Novemher 23d four miles had heen laid and a fair heginuing made at organizing. During tbe 32 working days following the latter date, there have been constructed 27 miles of road, over the most difficult part of the whole route between Yuma and Tucson. Just behind Old Mission Camp the train crosses three temporary bridges of crib-work, flanked hy heavy fills; two of these are 208 feet long, each, and nearly 15 feet high. The road cuts through the south end of the corral at New Mission Camp. At Rattlesnake hill it goes over a long fill of some 24,000 cubic yards; this work was done in three days, its rapid completion reflecting great credit on Stroubridge's skill iu bandling his forces.

The rapid progress made over the difficult country hetween Yuma and Gila, justifies Strobridge's assertion that he car, if required, lay tbe track over the comparatively easy country between Gila and Maricopa Wells hy April 1st, witb his present force. He does not now expect to consume over four months in doing that, in any event.

The line passes over the mesa about a mile and a quarter south of Fillihuster Station, which is 44 miles east of Yuma by the stage road. Coming from there by stage, as we neared Martinez camp, we saw, to the southeast, clouds of smoke raised by hrush-burners in advance of the graders. Fogs of dust soon indicated the whereabouts of the latter, strung along for several miles. Ahout a quarter of a mile south of Martinez was a group of tents occupied by teamsters and well-diggers, and a donkey engine emitting vigorous puffs of smoke and steam.

Salt Lake and Colorado River Railroad.

According to the Salt Lake *Tribune*, Jay Gould subscribes for one-half of the stock in the new railroad from Chicken Creek to Frisco, one-fourth is to he held hy the Mormons, and the remainder hy tbe Bonanza people. If that means the extension of the Utah Central south to the Big Bonanza mines, it is a most important railroad link. In Iron and Beaver counties, Utah, the mines of coal, iron, lead and silver are among the richest and most extensive in the Union. The coal is of so pure a quality that it is used for all purposes of the forge, and when coked makes the finest possihle material for fuel for smelting furnaces. There are now very extensive coking furnaces 150 or 175 miles south of tbe present southern terminus of the road, while tbe amount of ore which is rich in lead but not sufficiently rich in silver to justify freighting hy teams, is described as enormous. The Union Pacific Company now coutrol the road running south from Salt Lake City, and the exteusion would not only secure the trade referred to, hut would take from the Central Pacific all the trade of southeastern Nevada and turn it toward Salt Lake. It is a good project, and would return 100% on the capital necessary to construct and equip the road every 18 months.

Salt Lake and Idaho Railroad.

The Utah Northern has now heen extended from Ogden into Idabo, 200 miles. One hundred miles of this have heen huilt witbin the past year. Tbis road is opening up new fields of trade, which will grow as tbe line extends into Idaho and Montana. With this new route the trade of Oregon and Washington will be secured ultimately; but it is uow the intention of the company to push the road the coming season toward tbe rich mines and pastures of Idaho and Montana.

New Mexico Has Been Invaded.

The Denver and Rio Grande railroad has finally crossed the line from Colorado.

The project of offering homes in New Mexico, along the line of a proposed railway, is attracting some attention among workingmen in New York. Twenty-acre farms, with cattle and farming implements, are sold for $200.

One Remarkable Feature,

Says the *Railway Age*, of the western situation at present, is the movement of so many lines to secure a share of Colorado business. It is only about eight years since the first locomotive crossed the plains and reached Denver. Now tbree great trunk lines, the Union Pacific, Kansas Pacific and Atchison, Topeka & Santa Fe, run their trains thither, and two others, the Burlington & Missouri River in Nebraska and Central Branch Union Pacific, have started for the long race of about 400 miles across the plains to the same destination. The former of tbese has reached Red Cloud, Nebraska, and is pushing up the Republican river. The Central Branch road now runs to Beloit, Kansas, on the Solomon river, and an Atchison paper reports President R. M. Pomeroy as saying the line would be extended 100 miles west of tbat point "just as fast as an unlimited supply of money and men could do it," and that a through line to Denver was "an absolute certainty." It is not improhable, therefore, that within a few years as many as half a dozen independent lines may span the width of Kansas or Nebraska and reach the foot of the Rocky mountains. Tbe impulse for this great movement is the prospect of traffic from the new lands to be developed along the line, as well as in the mineral regions of the mountains, which are probably but commencing to reveal their wealth.

Mexican Lines.

From the American deputation now in Mexico, we learn that the Mexican government desires to connect the Atlantic and Pacific coasts hy a railroad from Tampico to San Blas, and is disposed to give a liberal subsidy in aid of tbe undertaking. At the Mexican capital, General Frisbie, is ahout to establish a hank which will conduct business on a broad and progressive hasis. It is likewise contemplated to organize a transportation company, which shall undertake hanking operations and enable manufacturers in the United States to transact business with safety and dispatch in the Mexican republic. It is likewise proposed to huild an internatioual railroad, which, beginning at the terminus of tbe Great Northern railroad at Austin, Texas, would pass tbrough Laredo, Saltillo and San Luis and terminate at the Mexican capital. An able document in support of this project has been published, and 2,000 copies thereof will he circulated in Mexico during the stay of the deputation.

The elaborate investigations made at Altoona by Prof. Charles B. Dudley, chemist of the Pennsylvania Railroad Company, of the chemical composition and physical properties of many old steel rails have led him to adopt the important conclusiou tbat they sbould bave, of phosphorus, not above 0.10%; of silicon not above 0.04%; of carbon between 0.25% and 0.35%, with an aim at 0.30%; of manganese, between 0.30% and 0.40%, with an aim at 0.35%.

A highly respected Russian embezzler—who stole a million dollars—has heen sentenced to six years penal servitude in Siberia.

MECHANICAL PROGRESS.

Transverse Strength of Materials.

The transverse strength of beams is a complex quantity, which demands *two* elements—its tensile strength and its resistance to crushing. This becomes evident when we consider that when a beam is supported at both ends and a load placed on top of it, the fibers in the lower part will be extended, while those in the upper part will be crushed together. Between the two there will be a line, or rather plane, in which there will be neither extension nor crushing. This line or plane is called the neutral axis. When a beam is solidly fixed with one end in a support and the free end loaded, the inverse action takes place—the upper fibers will be extended or stretched, while those below will be subject to crushing strain; but here also there is a neutral axis, or a line between, where neither extension nor crushing takes place.

It has been laid down in some treatise on mechanics that this neutral line is always half way between the upper and lower part of the beam; but this is evidently erroneous, or at least an incomplete statement, as the section of the beam has an influence; if the section at the upper part is larger than it is at the lower part, it will have more strength, and *vice versa*, hence the neutral axis must be higher or lower than half way. It is more correct to state that the neutral axis passes through the center of gravity of the cross section, thus in a triangular beam, with the apex on the top, it would be at one-third of the hight instead of half way.

But this statement also is incomplete, as it leaves out of account the difference in crushing and tensile strength, which some materials may possess. If, for instance, we have a hard alloy like bronze, with great power of resisting crushing pressure, but with a comparatively small tensile strength it is evident that when submitted to transverse strain a gradual increase of the same will submit more fibers to tensile strain, for the reason of the greater resistance to crushing strain, and the neutral axis will necessarily lie nearer to the part compressed by the effect of the load, and further from the side where there is the greatest tensile or extensive strain.

This is the reason why it is unreliable to deduce the transverse strength of materials from the combined action of their tensile strength and power of resistance to crushing strain, and separate apparatus are used for the purpose of finding the transverse strain, directly by experiments. Such an apparatus has recently been devised by Prof. R. H. Thurston, of the Stevens Institute, Hoboken, N. J., who, as is well known, is foremost in his experiments on this subject, so highly important in practical mechanics.

Steam-Boiler Inspection.

The Hartford, Conn., Steam-Boiler Inspection and Insurance Co. is doing a good work. In a recent communication from Mr. F. B. Allen, the President of that Association, to the *Manufacturer and Builder*, the question—"Is Government Inspection of Steam-Boilers a Failure?" is discussed at some length, and a comparison is drawn between the efficiency of government inspection and that of the company, that is decidedly to the discredit of the Government Board of Supervising Engineers. We give herewith a summary of the facts presented, representing the same number of years (1870–1877) in the two classes of work:

U. S. Board of Supervising Engineers.

Total number of boilers tested	42,473
Total number of lives lost by explosion	667
Total amount of property destroyed by explosion	$623,514

Hartford Steam-Boiler Inspection and Insurance Co.

Total number of boilers examined	56,145
Total number of lives lost by explosion (since organization of the Company, 12 years)	25
Total amount of property losses	$74,381

Mr. Allen, from the above showing, draws the inference, that Government inspection of steam-boilers is a failure. We do not see how any other inference could well be drawn.

LOCOMOTIVE BUILDING IN 1878.—Locomotive building during the past year has shown quite an improvement over the two or three previous ones. Statistics show an increase of from 35% to 40%. A large portion of this increase has come from foreign orders. During the year, locomotives have been shipped to Russia, Brazil, Peru, Cuba, Nicaragua, Norway, Italy, Australia, and New Zealand. Forty have been sent to Russia alone. These distant and diverse shipments indicate the establishment of a permanent foreign trade in this important branch of industry. The shipments this year to either Norway or Sweden are the first ever made. The great reduction in price is also a most noteworthy fact connected with this business. Prices have had a shrinkage of fully 50% during the past five years. Locomotives which cost $10,000 in 1873 can now be bought for $5,000. Cost of production has decreased largely, but not in proportion to selling prices. It was stated in a late number of the *Iron Age* that the Baldwin Locomotive Works had just received *by cable*, from Europe, an order for nine of their largest-sized locomotives.

The Need of a Standard Screw-Thread.

Any one who realizes the important part performed by bolts and nuts in railroad machinery, would naturally suppose that a standard system of screw-threads would have been practically as well as formally adopted long before this. Such, however, is not the case, so far at least as the practice is concerned, and consequently the great advantages to be derived from such a system have not been realized. The Master Mechanics' and Car-Builders' Associations adopted what is known as the Sellers or Franklin Institute system, several years ago, but owing to an imperfect understanding of it the desired uniformity in the threads and diameter of bolts has not been attained. One peculiarity of this system is that the screw-threads, instead of terminating in a sharp edge or point, are made flat at the top and bottom, and the pitch is fixed at an inclination of 60 degrees. By doing away with the pointed or V-shaped thread, the diameter and consequently the strength of the bolt are increased without lessening, to any extent, the strength of the thread. The diameter of the bolt can also be measured with greater accuracy for the reason that the depth of the sharp thread will vary as the point of the cutting tool wears. A sharp edge is also more liable to injury than are the threads with flattened tops.

A table of "Standard Screw-Threads," adopted by the Car-Builders' Association, at Richmond, Va., 1871, has been printed in most of the annual reports of the association since then. This table gives only the outside diameter of bolts and the number of threads to the inch, as being all that is essentially implied in the system adopted. The result has been that different taps and dies for the same size of bolt are in use on different roads, the diameter of the screws and the form of the threads not being alike in many instances. This is owing to the fact that only a part of the dimensions specified in the Sellers system have been adhered to, regardless of the fact that no uniformity by which such bolts can be made interchangeable can be had, unless every requisite of the system is strictly carried out. The angle of pitch, length of sides of thread, diameter of bolt at bottom of thread, and width of flattening at top and bottom, are all equally necessary in order to secure good fitting and interchangeability. This may be obtained by the use of a proper gauge for grinding the tools for cutting the threads, and by having all taps and dies conform exactly to the standard. A more detailed account of the Sellers system, illustrated with cuts showing the form of threads, bottom of gauge, etc., will be found in the *Car-Builder* for August, 1877, and also in "Forney's Catechism of the Locomotive."—*The National Car-Builder.*

STEEL NAILS.—That iron is slowly but surely being supplanted by steel is an important fact, but probably few would think that the familiar wrought-iron nail is destined to be replaced by a steel one. Yet this appears probable, and Messrs. Jones Brothers & Co., of Middlesborough, are entitled to the credit of being pioneers in this improvement. The difference in price between steel and iron is of absolutely no consequence in an article of this kind, while the superiority in quality is in many cases of considerable importance. The nails which we have seen are of several varieties, and the toughness of the metal is very remarkable. A nail selected at random is capable of being bent upon itself cold, while it is firm enough to go into the hardest wood. Considerable pains is taken by the makers to give not only a good head, but a good shape throughout the length, so as to avoid the wedge action of too many cut nails, which tends to split the wood in which they are being driven just at a critical moment. These nails are made by special machinery, which certainly seems to do its work very well, and they are in every respect well worth a trial by all who are dissatisfied with the nails commonly sold.

IRON GALVANIZING FURNACE.—In galvanizing iron the main point to ensure a uniform coating of zinc is the maintenance of a thin bath of metal. Unfortunately the zinc absorbs iron, thickens, and as the temperature must be rapidly raised, when it does so this absorption goes on increasing until the metal is unfit for further use. This is aggravated by the fact that the metal is melted in cast or wrought-iron vessels heated from below. *Iron* says that in order to avoid the disadvantages of iron vessels, and yet retain ample working space above the surface of the metal, F. A. Thum, of Laubach, Germany, has constructed a furnace resembling somewhat a reverberatory furnace. It has a fireplace and a chimney at each end, the part of the hearth connecting the two being arched over. The rest of the rectangular hearth is perfectly open above, so that the heat-conducting power of the metal is relied upon to keep it at the proper temperature in that part of the hearth. The slabs of fresh zinc are introduced through doors communicating with the hot ends. The staying of the furnace has to be very strong, in order to prevent any accidents to the arching over the ends of the hearth.

RAILROAD PATENTS.—It is said that there are now more than 165,000 American patents alive which relate to devices used for railroad purposes—1,700 of which are upon car-couplers.

SCIENTIFIC PROGRESS.

Mountain Making—How the Alps Were Formed—Geological Theory.

Prof. Judd, of the Royal School of Mines, London, gave recently an interesting explanation of the formation of the Swiss Alps. The results of geological observations, he said, show that four stages can be recognized in the history of these Alps. First, the existence of a line of weakness in the earth's crust nearly coincident with the line of the present mountains. This is evidenced by the fact that along this line of weakness there were volcanic outbursts, the result of which can still be traced. Secondly, there followed along this line of weakness a depression, and in this huge "trough" of miles in extent there accumulated sands, limestones, and clays by various forms of water agencies, and by animals living in the waters. Thirdly, there followed the consolidation of these soft and loose materials. There is evidence that the accumulation was of from six to seven miles in thickness, and the mere weight of the superincumbent material on the lower strata would have a share in effecting consolidation. But this was not all. Under this vast covering heat had led to crystallization from fusion. There was, too, the crushing in from the sides of the trough. This was illustrated by a model of the late Sir H. de la Beche, where lateral pressure was employed on layers of different colored cloth, showing how crumpling resulted, with uplifting of parts of the accumulated mass. Fourthly, there had been the sculpturing of all this into its present form, which was the work of rains and frosts. Some of the existing peaks, even 3,000 feet high, were composed entirely of the disintegrated material resulting from the action of the water, either as ice in glaciers or as rain and streams. The amount of material removed in this was so stupendous that it was almost staggering to try to grasp the facts. The sculpturing of the contours is still going on. This fourth stage was of quite recent date, speaking geologically; but the whole history involved a lapse of time which at the beginning of this century philosophers would not have been prepared to grant, even if the since-acquired knowledge of facts had been presented to them.

THE LIGHT FROM VENUS AND MERCURY.—Quite a singular and most unexpected discovery was made at the near approach of these two planets in September last, by Mr. James Nasmyth, an English astronomer. It remains to be seen whether photography or spectrum analysis will some day give us the key to the enigma. The fact was then first distinctly observed that there is a great difference between the degrees of brilliancy emitted by these two planets; and, that while Mercury being much nearer the sun should be more brilliant, just the contrary happens, for Venus shines with the greater luster. On the 26th and 27th of September these two stars were near enough to be embraced within the field of the lens at the same time, and Mr. Nasmyth was thus enabled to compare the brilliancy of Venus to polished silver, and that of Mercury to lead or zinc. The reason of this difference, which is theoretically exactly contrary to what we should expect, is at present unexplainable.

LIQUEFACTION OF OXYGEN.—M. Raoul Pictet concludes an article on the liquefaction of oxygen with the remark that his investigations necessitated an unusually large number of experiments for the establishing of preliminary data, and these he obtained by the aid of the Geneva Society for the Construction of Physical Instruments, who furnished him with apparatus worth 50,000 francs, and thereby enabled him to work out results with perfect accuracy. He recommends that similar apparatus should be provided in all laboratories as an "essential means for the study of the molecular forces. Who knows," he asks, "but what crystallization and certain reactions may thereby be placed in peculiarly favorable conditions for further investigation?"

ELECTRICAL TELEGRAPHING WITHOUT WIRES. Prof. Loomis continues his experiments in the mountains of West Virginia, to demonstrate his theory that at certain elevations there is a natural electric current, by taking advantage of which telegraphic messages may be sent without the use of wire. It is said that he has telegraphed as far as eleven miles by means of kites flown with copper wire. When the kites reached the same altitude, or got into the same current, communication by means of an instrument similar to the Morse instrument was easy, but ceased as soon as one of the kites was lowered. He has built towers on two hills about 20 miles apart, and from the tops of them has run steel rods into the region of the electric current.

IMMENSE GLACIAL REMAINS.—Prof. T. V. Hayden says that on the east side of Wind River peak, Wyoming Territory, and on the east base of Fremont peak, the remains of the huge glaciers which once covered the region have been discovered. On the west side of Wind River range, the moraines and glaciated rocks were found on an immense scale. He thinks that on this side a glacier must have formerly existed having a length of 80 miles and a width of 12 miles with arms extending up the gorges of the streams to the very water divide.

IS THE SUBDIVISION OF ELECTRIC LIGHT A FALLACY?—Mr. W. H. Preece, the eminent electrician and manager of the English postal telegraph system, contributes a paper to the *Philosophical Magazine*, in which he points out that the theory of the electric light cannot be brought absolutely within the domain of quantitative mathematics, for the reason that we do not yet know the exact relationship existing between the production of heat and the emission of light with a given current. We, however, know sufficient to predicate that what is true for the production of heat is equally true for the production of light beyond certain limits. He shows that the full effect of a current can only be obtained by one lamp on a short circuit, and that when we add to the lamps by inserting more of them on the same circuit, or on a circuit so that the current is subdivided, the light emitted by each lamp is diminished in the one case by the square, and in the other case by the cube, of the number inserted. With dynamo-electric machines there is a limit which has to be reached before this law begins to act, and it is this fact that, in Mr. Preece's opinion, has led so many sanguine experimenters to anticipate the ultimate possibility of extensive subdivision of the light—a possibility which he considers hopeless, and which experiment has hitherto proved to be fallacious.—*Scientific American.*

THE ELECTRIC LIGHT DANGEROUS.—Mr. J. M. Stearnes, Jr., of Brooklyn, points out a novel source of danger possible with the electric light, namely, its effect upon the nervous system. He says: "The very high penetrating power of light waves from incandescent metal or carbon heated by electricity is well known. It is so high, indeed, that the shadows cast by the light are blacker than Erebus, indicating an immense absorption of force by the intervening objects, and to a large extent destroying their reflection and diffusion, as is the case with lights of lesser tension. A reflector used with an electric or calcium light does not produce anything like a corresponding effect as when used with a common gas flame, as persons familiar with calcium lights well know. And it follows, therefore, that the black shadows of the electric flame must be due to the absorption of light waves. Now, in the light of an electric arc or incandescent lamp, one is to be subjected to a very powerful stimulant from the mere obstruction which his body affords. Our eyes cannot bear it all, and there is no reason to doubt that every nervous tissue will feel its use. We have already in this climate enough of nervous stimulation, and a fearful catalogue of nervous diseases, arising from too much force."

GEOLOGICAL.—The *Polytechnic Review* learns through a private letter from Dr. T. Sterry Hunt, that the Geological Congress at Paris was a great success. There were 260 members present; and various committees were formed, the work of which will prove highly important and useful. Arrangements were made for a Congress, to be held in 1881, at Bologna. From another source we learn that Dr. Hunt has returned from England, and will spend the winter in Montreal, Canada, where, as scientific men will be interested to hear, he expects to devote himself to important scientific investigations. Before leaving England, he accepted an invitation to deliver two lectures at Cambridge—a graceful and merited recognition of the ability and reputation of an American *savant*.

INSTANTANEOUS PHOTOGRAPHS.—The success of Mr. Muybridge of this city, in taking a number of *instantaneous photographs* of a horse at full speed have attracted much notice, not only at home but also abroad. M. Marey, in *La Nature*, who has made extended investigations upon the subject of the analysis of animal motions, appears to have been greatly struck by the pictures of Mr. Muybridge, and believes that his success provides an admirable means of studying in every successive position of motion the very difficult problem of the flight of birds. "What beautiful zoötropes," he suggests, "might be obtained by this method. We might see in their true paces all sorts of animals; it would be a sort of animatic zoology. As to artists, it is a *revelation* for them; for it furnishes the true attitudes of motion; those positions of the body in unstabled equilibrium in which a model cannot 'pose.'" In connection with this last point, it may be of interest to notice that many of the attitudes exhibited by Mr. Muybridge's pictures are very unlike the stereotype ideal.

SOALR AND ARTIFICIAL HEAT.—Prof. S. P. Langely, Director of the Alleghany Observatory in addition to the routine work connected with the institution over which he presides, has lately been busily engaged in completing a direct experimental comparison between the heat of the sun and the highest heat attainable in the arts. The result of his investigations indicate that the sun's *intrinsic* heat is almost beyond comparison greater than that of any blast furnace, and far larger than has been reckoned by the French physicists.

MR. LOCKYER'S RECENT PAPER.—The last number of the *American Journal of Science* contains Prof. Lockyer's paper in full, on the "Dissociation of the Elements," as read before the Royal Society of London, on the 12th of December last. The paper is entitled by the author, a "Discussion of the Working Hypothesis that the so-called Elements are Compound Bodies." The paper is quite fully illustrated.

Mining Share Market.

The stock market seems to lack symmetry. It is out of shape, irregular in its movements and uncertain in ite interests. One day a move is made in a particular eection of the Comstock, and tho market becomes euthusiatic; then all of a sudden, without waruing this section is dropped, and becomes flat and dull, while another epot is chosen to go through the eame routine. The week opened very quietly and the dullness continued throughout. There was an occasional wave, but it was scarcely more than a riffle. Early in the week there was a slight rise in Ophir and a decline in Jacket and Sierra Nevada. The deal in Yellow Jacket seems to have worn out its chief manipulators entirely. Deeperate efforts have been made to entbuse tbe market, but the outside is decidedly wary, while the ineiders have been careful not to state that the movemente aro hased ou the actual development of the mines, tbey have given out that Eastern men are liable to become good customers, and that along the Comstock there never were better indications, etc., till eome, at least, have been led to invest. Here, perhaps, lies the eecret of the wavering etate of the market. Everytbing is "indications," and nothing but indications. People will not inveet their money largely on the mere possibility thus expressed. At tho close, there was a slightly firmer eondition of the market, with a riee in Union and Sierra Nevada.

Bullion Shipments.

Since our last issue, we have noticed the following bullion ehipments:

Tybo Con., Feb. 10th, $4,277.54; Christy Con., Feb. 11th, $4,968; Highbridge, Feb. 14th, $8,108; Hillside, Feb. 15th, $5,020; Independence, Feb. 17th, $6,000; Paradise Valley, Feb. 17th, $3,390; Grand Prize, Feb. 16th, $12,500; Ophir, Feb. 10th, $22,343.81; 15th, $23,110.28; Con. Virginia, Feb. 15th, $41,696.70; Extra, Feb. 4th to 15th, $7,326; Christy Con., Feb. 18th, $6,199; Hillside, Feb. 19th, $5,580.

ARTESIAN WELLS FOR ARIZONA.—We have long advocated the sinking of artesian wells, believing tbe character of our valleys and mountains warranted the belief that siuking would result in succees. In this connection our many readers will no doubt be happy to learn, that Col. C. P. Sikes, manager of tbe Calabasas Land and Mining eompany, bas just eompleted tbe purebase of a eomplete maehinery for boring of artesian wells upon their property at Calabasas, and it is now in transit from Joliet, Ill., and expected to arrive here eome time next montb. This machinery and tools, witb all the beet modern improvements and appliances for drilling rapidly, and to a great depth, will be accompanied by Mr. Jas. McQuiggle, as superintendent. Mr. Jas. McQuiggle, we learn, is a man of great experience in "well drilliug," througb all kinde of ground and rock. Tbe work of tbe drilling will be commenced in March upon the town site of Calabasas. Tbis work wben commeuced will bo vigorously pusbed, nigbt and day, until flowing water is reacbed, if iu order to do that they have to go dowu to a deptb equal to that of tbe level of the sea.—*Arizona Star.*

STATIONARY POWER FOR THE MILLION.—By referenee to another eolumn, it will be seen that tbe Pacific Power Company advertises a room with steam power to let in their new building in tbis city. This is a good opportunity for machinists and small manufacturers, and ougbt to be a great convenieneo botb to tbem and otbers, whose husiness ealls for a ebeap but at the same time limited power for propelling lathos and otber macbinery necessary to such trade. Steam-motor power ou a small scale is not alwaye obtainable, and this offer will be a bonanza in the hands of an enterprising man, and mueh economy and saving will be effected by its acceptanee.

THE great undertaking of penetrating the Alps with a tunnel at St. Gotbard has now progressed 40,443 feet, or 7.65 miles. There etill remain 9,000 feet, or 1.74 miles to be bored, wbicb it is boped to complete in a year, making tbe tuunel nearly nine and a half miles long, by far the most gigantic work of the kind. The original estimate for tbe work was $17,000,000, but it is now expected to cost no less than $45,000,000.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

THE MONTERICHARD.—*Dispatch*, Feb. 15: Drifts are being run at the 250 level; the ledge maintains its width of from two and a half to three feet, and the rock looks still better than that takeu from above. The mill ie constantly running, but another clean-up will not be had till the first of next month. The regular pay day will uot be interfered with by the recent etopping of the mill.

THE ONEIDA.—This mine is running ouly 20-stamps. The indicatione are favorable for it to soon reach its former prosperity. Quite a handsome shipment of bullion was made a few days ago.

THE MOORE MINE.—Everything looks encouraging at this mine, the ledge being ahout eeven feet, and tbe rock above tho average grade. The mill is now running in good style.

DOWNS.—*Ledger*, Feb. 15: This mine continues to yield largely. The rock taken from it has yielded a higher per ceut. of gold than any worked in Amador county for many years. A clean-up was made in tbe early part of the week, from 105 tons of rock. The bullion obtained was $5,000; within a fraction of $50 per ton. The levels look as well as ever; all the indications favor the idea of a permanent mine.

CALAVERAS.

THE SHEEP RANCH MINES.—*Chronicle*, Feb. 15: Rock of extraordinary richness is being taken from the Chavanne mine, the shaft having reached tbe depth of 400 feet. The ledge is developing splendidly. A fine mill is owned in connectiou with the mine, which is now at work and will be kept constantly employed in the future. At the well-known Wallace & Ferguson mine, the new 20-stamp mill is in full operation. Since the work of re-timbering tbe shaft was completed operations have been greatly facilitated and conducted witb increased energy and vigor. It gives employment to about 75 men and crushes, ou au average, 35 tons of high grade ore per day.

MINING SCRAPS.—The shaft in the Champion at West Point is in 500 feet. This gives the mine a hundred feet of backs—roek euough to keep tbe mills running iudefinitely. At tbe San Pedro, Glencoe district, the new shaft is down 105 feet and the pumps and hoisting works are in position ready for operations. Water bas heen struck in the shaft, but the new machinery is sufficient to prevent inconvenience from that source. At tbe Banner, a crusbing of 160 tons of ore in Garland's mill bas been lately completed.

MONO.

THE STANDARD CON.—Bodie *Standard*, Feb. 14: There is probably no truth in the rumor that the Standard and Bulwer companies have consolidated their interests uuder a new incorporation. It is more tban likely that the new incorporation implies a consolidation of those intereets held by the original Standard company by deed, acquired subsequent to the first ineorporation. Whetber tbis iucludes all of the West Bullion ground, we are not quite certain, but believe such to be the case. The new main sbaft is located in this subsequently acquired territory, developments in wbich have been so valuable as to practieally double tbe value of tbe entire Standard property, to say nothing of the new finds in the original ground east of tbe main lode. Altogetber, tbis is probably tbe correct theory of the new incorporation, witb 100,000 instead of 50,000 sbares. Tbe *Chronicle*, February 13th, says of this mine: There bas been no ebange in the east crosscut from main shaft. Tbe total leugth is 219 feet—progress for the week, 31 feet. South drift from this erosscut has been extended during tbe week 20 feet—total length, 175 feet. The ledge is three feet wide and looks well. The east crosscut (300 level) is in 195 feet—progress since last report, 17 feet. No change in the ground passed through. North drift from this crosseut bas been run 19 feet duriug the week; length 35 feet. The ledge is two feet wide of good ore. Nortb drift on West Standard is in from crosseut, 44 feet; the ledge is two feet wide and looks well. Ledge in south drift is 18 incbes wide of good ore. The drift is in 52 feet. Nortb drift on Cook ledge is in 110 feet from soutb line. Ledge is 18 incbes of very good ore.

BULWER.—Tbe ledge in tbe south drift (300 level) is three feet wide aud looks well. Tbis drift is in from the winze 140 feet. The ledge in upraise is two feet wide of good ore. Have resumed work in eouth drift (200 level). The ledge is two feet wide and looks well. The Stonewall stopes are looking as well as nsual.

TIOGA.—Opened 420 station and started east drift, which is in ten feet. Sinking helow tbe 420 station—down 18 feet, and continuing west crosscut at 320 level. Ground in sbaft eontiuuing about the same, but more favorable for working.

JUPITER.—Shaft down ahout 240 feet; ten feet more aud a statiou will be opened.

MONO.—Drift at 400 level in 26 feet. Not sinking on account of water, of which 40,000 gallone are daily disebarged. Troublesome nature of ground prevent rapid headway.

CON. PACIFIC.—Work on this mine during the past week was ehiefly centered upon tbe winze sinking on lode No. 2. This winze is 63 feet from the mouth of tbc old tunuel, 3½x7 fect in size and nearly 50 feet in depth. The ore holds out fully in quantity—20 inches in width—and is improved in quality. A crosscut east to No. 1. and a winze thercon is projected. This will develop the property pretty thoroughly, aud enable the company to extract an abundaut and regular supply of ore until the new shaft south, and its connections, are established. A whim is to be erected and the work of siuking and timbering coutinued.

NEVADA.

PLUM VALLEY MINE.—*Herald*, Feb. 15: The buildings for the hoisting works and the mill are completed, and the machinery being rapidly placed in positiou. Everything will be in running trim in threo wceks. J. C. Culver, Esq., former President of the Masouic Savings and Loan Association, is Superiutendeut of the mine. The mill contains 10 stamps and gold-saving apparatus of the latest and most improved kind. It is estimated that the rock can bo worked at an expense of $3.50 to $4.00 per ton. There is a large quantity of ore in sight that will yield $15 or more per ton.

BLOOMFIELD ITEMS. The North Bloomfield company have their mine running in full blast, with tbree monitors throwing their huge streams against the gravel banks. Brockmeyer & Co. have plenty of water now, and are rushiug off the gravel from their claim. Tbe Derbec mine ie hoisting its regular quantity of rich gravel, and has uo trouble in getting water to make its washings.

THE INDEPENDENCE LEDGE.—Grass Valley *Union*, Feb. 16: The old Independence tunnel, a few hundred feet west of the old Gold Tunnel company's mill, is now being re-opeued and worked by Meesrs. Damon & Prentice. A shaft sunk from the top of the hill ie down 200 feet. Their object is to connect tbe shaft and tunnel to give a free circulation of air. They have already a well-defined ledge of 10 inches, the last crushiug of which paid $50 per ton.

DAMAOE TO A MINE.—The Nevada Hill (lately the Bell) mine, recently shut down for the season on account of the inability of machinery to haudle the eurface water, whicb flowed in freely. Since the late etorm the ground around the ehaft indicates that there has been serious caving in the underground workings, the extent of which cannot be ascertained until the mine is again pumped out.

PLACER.

IOWA HILL ITEMS.—*Herald*, Feb. 15: Water is greatly needed in this locality. Tbe mines are worked by the hydraulic process, and therefore it is an indispensable necessity. Last Saturday the Orient Mining Co. eet off a bank blast of 165 kegs of Hazard powder; it was in tbree chambers; was exploded by electricity, aud was very effectual. The Iowa Hill Canal Co. have 50 men digging a ditch from Humbug canyon, a distanee of six miles, designed to bring water to their large reservoir a little above Iowa Hill, from which a number of mines, besides their own, get their supply of water.

PLUMAS.

MINING NOTES.—Butterfly Cor. *National*, Feb. 8: The Bushman claim is ruuning a drift on good pay gravel, but working under great disadvantage, owing to the depth of the ehannel, but has very flattering prospects. Horace Smith, working a short distance below Bushman, is tunneling to strike a chaunel left when the main Blackhawk was first worked. The Blackhawk miuing claim is uot at present working, owing to the cold weather, but ie prepared to make a good showing as soon as the weather moderates. On tbe Blaekhawk Bar, Mr. Robert Holmes is working over tbe old bedrock, results not known. On the Barker ravine, Messre. Whitney & Weatherby bave run a bedrock tuunel a distance of 100 feet or more, and have etruck gravel that prospects good to every pan. Bowers & Co. are working iu very good gravel. Over on the Butterfly side is the placer claim known as the Mound elaim, worked by Kimball, Crowell & Co. They are working from an ineline, bave considerable pay dirt on the dump, and are anxiously waiting for tbe rain.

SHASTA.

VARIOUS CLAIMS.—Inyo Cor. Reading *Independent*, Feb. 13: In the South Fork district there is a decided improvement; work is going ahead in good earnest, tbe excitement steadily inereasing. Tbree more very ricb gold-bearing ledges bave been discovered, on which good forees are hard at work. A specimen from one mine was literally covered with free gold. A few loads of such quartz would satisfy almost any reasonable man. Mr. J. P. Wright and Anderson & Co. are taking out the same kind of ore from tbeir new mine, the Sherman. The ledge is about four feet thick and prospects well all through. The gold is fine, but in abundanee. O. Eugle is now drawing ore from his Dayton mine, whicb is being reduced by Mr. Peck. Balou & Hubbard havo got their arastra completed and are now taking out and working ore from their own mine. Up tbe hill Mr. L. Provost & Co. are running a tuunel to etrike and cut tbe Detroit mine deep down.

TRINITY.

BULLYCHOOP DISTRICT.—*Journal*, Feb. 15: The Bullychoop aud Occidental tunnel is now in 150 feet and progressing favorably, although only about two feet is being made in 24 houre, owing to the bard cbaracter of tbe roek. A good traek is laid in the tunnel and a car run thereon. Other companies in the district not doing much at present. Mr. St. Clair has a four-etamp mill ready to hegin operations as soon as the snow goes off and a pipe ean be laid. John R. Knox has 100 tons of good rock from the Central Lode, which he will have crushed at the mill. The Rattlesnake and Excelsior company is down ahout 50 feet in each mine and find the lodes three feet wide, from wbich they obtain excellent prospects. Sillcox & Co. have found a new lode on the other side of the hill, which they have christened tbe "New Jerusalem."

NEVADA.

WASHOE DISTRICT.

Our usual Washoe letter haviug failed to come to hand iu time for this issue, we substitute, therefor, latest letters received by the various companies in this city from superintendents on the Cometock—the dates mentioued, being all of the present month.

CALEDONIA.—Letter of 15th: During the past week the east drift has been extended 28 feet, and the vertical winze has been suuk and timbered 20 feet; the formation in east drift is mucb harder than it was the first part of the week.

ALPHA.—Letter of 16th: The situation at the mine continues the same as last reported. The flow of water from the face of tbe joint drift on our 2400 level (east) contiuues about the same, hence we have not yet resumed work at tho point.

CHOLLAR.—Letter of 15th: At the Chollar-Norcross-Savage shaft has been sinking steadily during the past week, and the work has made good progrese, considering tbc large amount of water—eome 71,500 gallous per day tbat we have hoisted. Rock on west side of shaft is somewhat harder.

JULIA.—Letter of 15tb: Slow progress has been made in lowering the accumulated water which bas risen above 2000 level. It is now antieipated from the general aspect of everytbing connected with tbe pump and rode, that the result will be more satisfactory at tbe eud of the coming week.

MEXICAN.—Letter of 15th: The joiut Union Con. winze on our 1605 level has been eunk and timbered 14 feet during the past week; total depth, 224 feet on slope. The material passed through has become extremely hard rock. On our 2000 level the main north drift has been advanced 63 feet; total length from our south line 424 feet. No change in material.

BEST & BELCHER.—Letter of 16th: The 1700 level joint east drift was extended 36 feet during the week, and is now in 508 feet. West joint crosscut 1900 level was advanced 20 feet, and is now in 84 feet. Tbe face ie in a mixture of quartz and porphyry, but assaye notbing. Owing to the strong flow of water the Osbiston shaft was only eunk 10 feet. It is now down 460 feet in good sinking grouud if it was dry. Everything is working well.

HALE & NORCROSS.—Letter of 17tb: Yesterday at 9 A. M. tbc pump rod at the second pump broke, eince tben the work of repairing the rod has been going ou and will be completed some time this eveuiug. The water stands 50 feet below tbe 2000 level. The winze down from 2000 level is now 20 feet deep; considerable water is coming in.

BULLION.—Letter of 17tb: During the past week we have opened a station in the incline at tbe 2150 level, from this station we will start a drift south during the first part of tbis week to connect with the 2000 level of the Imperial. Tbis connection will be made hy tbe first day of March, barring accidents. Tbe formation in the roof of the incline is soft vein propbyry aud low grade quartz. On the 2400 level the combination Bullion-Excbequer drift bae heen advanced a distanee of 28 feet, making ite tetal lengtb 167 feet. Tbe formation still contiuues the same favorable cbaracter. Everytbing about tbe miue running well.

WARD.—Letter of 15th: The east erosscut, whieb was started on Monday last, has been advanced 22 feet to date; total length, 424 feet. On fore part of the week the general ebaracter of the ground encountered consisted of large blocks of bird'e-eye porpbyry. The past few days, however, a change has taken place of a softer nature, containing clay and streaks of quartz.

BELCHER.—Letter of 15tb: To the length of the south drift on tbe 2360 level 30 feet have been added tbe past week; total lengtb, 669 feet. The south drift from the 2560 station is now in 83 feet, having been run 45 feet the past week. The 2560 etation is about finiehed and the ventilation on this level is now excellent, owing to tbe connection made with tbe Crown Point.

UNION CON.—Letter of 15th: Mexican joint winze on 1600 level has been eunk and timbered 14 feet during past week—total deptb 224 feet on slope. Material eucountered is extremely bard rock. Still ongaged in work of repairing aud wideniug 1450 Sierra Nevada drifts. Flow of water from east drift has decreased to about three and a half inches.

OVERMAN.—Letter of 15tb: Sinee our last report the vertical winze has been sunk and timbered 19 feet; north lateral drift bas beeu extended 31 feet; face is in a promieing eharacter of quartz. Tbe new ebaft bas been sunk and timbered 20 feet. Tbe water coutinues very troublesome. We bope to get tbe ekeet running by the last of the week, and then we ean handle the water without mnch tronble.

GOULD & CURRY.—Letter of 15th: For tbe past week the east drift on tbe 1700 level was exteuded 36 feet, and is now in 508 feet from the lateral drift. On tbe 1900 level the differ-

The Cone-bearers, or Evergreen Trees of California.—No. 5.

[Written for the PRESS by J. G. LEMMON.]

Cypress, Arbor-Vitæ, Cedar, Redwood, and Big Tree.

Tribe II. (of the first great order of *Pinaceæ*.) *Cupresseæ*—Cypress family. Cones composed of a few peltate or thickened scales. Leaves small, scale-like, pointed. A large and interesting family of 4 gencra and 10 species, separated by characters of the cone into two sections.

Section A.—True Cypress.

Cones with the peltate scales opposite on a depressed axis. Three genera and eight species.

First genus *Cupressus*, a classical name, or from the is'e of Cyprus, where it is abundant. Ornamental trees found on or near the coast; cones small, globular, knobby; 6 species.

1. *Cupressus macrocarpa*, Hart. "Monterey cypress." Tbe popular lawn and border tree of the coast towns. A symmetrical, conical tree, 20 to 60 feet high, with dark green foliage, hearing profusely large (1 to 1½ inches tbick) persistent cones, composed of a few pairs of pyramidal scales, the interstices filled with numerous angular, black seeds.

2. *Cupressus McNabiana*, Murr. "McNab's cypress." Resembles described species, but is smaller, 10 to 20 feet high, with denser, shining foliage; coues one-quarter to one-half inch.

3. *Cupressus Lawsoniana*, Murr. "Lawson's cypress." Resembles *C. macrocarpa*, but with finer, recurved foliage, and smaller (one-quarter inch) cones. "The most graceful and pleasing cypress known."

4. *Cupressus Nutkænsis*, Hook. "Yellow cedar." A valuable timber tree of the northern coast, 80 to 100 feet high; cones the size of peas.

5. *Cupressus fragrans*, Kellogg. "Port Orford cedar, or ginger pine" of the Oregon coast, and sparsely reaching California. A noble tree, 100 to 150 feet high, yielding valuable aromatic timber for cabinet work. Cones very small.

6. *Cupressus Goveniana*, ——? "Dwarf cypress." A favorite tree, or, rather, shrub, 10 to 15 feet high, and fruiting when very young. Cones the size of small peas. The species *Lawsonia* and *Nutkænsis* have been put into another genus hy some, and called *Chamæ cyparis*.

Arbor Vitæ.

Second genus *Thuja*, from the Gr. *thuia*, to smell, alluding to its odor. "Arbor Vitæ" (improperly called "White cedar" at the East). Beautiful trees, with fan-shaped foilage placed vertically; leaves in opposite pairs, small, imhricated and unequal; cones, ovate and leathery. Only one species in California—on the northern coast.

Thuja gigantea, Nutt. "Giant Arbor Vitæ." A noble and valuahle tree, often attaining 200 feet, with a diameter of 10 to 15 feet; timber, very soft and durahle; cones, one inch long, of four pairs of scales.

Cedar.

Third genus *Libocedrus*, from *libanus*, incense, and *cedrus*, the cedar. "Incense cedar." Symmetrical trees of slow growth and fragrant timher. Foliage, fan-shaped, hut placed horizoutally; cones, elliptical, of four to six very dissimilar pairs of scales. Only one species in California, widely but sparsely dispersed over all its mountain rauges at low elevations.

Libocedrus decurrens, Endl. "Post cedar." A handsome tree of pyramidal outline, fast tapering upward. Timber splits easily, endures exposure to weather, as fence posts, or takes a fine polish in cabinet work. Leaves in opposite unequal pairs and decurrent on the flattened hranches (whence the specific name). Cones, elliptical, one inch long, of six scales in three very dissimilar pairs, the second pair longest and fertile, hearing each two long-winged seeds.

Section B.—Taxodiæ, Redwoods.

Cones, elliptical, ohlate, of few pyramidal, peltate scales, disposed spirally on an elongated axis, though the cone may he globular, as in the *Taxodium* of the East. One genus of two gigantic species peculiar to California, alone representing a past prodigious flora.

The generic name *Sequoia* was given hy Endlicher hecause this genus is a lone follower (*sequi*, to follow) of vast colossal forests. By others said to he derived from "Sequoya," the celebrated Cherokee Indian; hut this is no douht an afterthought and unworthy to he kept up.

Redwood.

1. *Sequoia sempervirens*, Endl. "Redwood" of a limited section of the Coast range 100 miles north and south of the Golden Gate. This immense tree, only exceeded hy the other species—*S. gigantea*—often attains a hight of 200 to 300 feet, with a circuit at hase of 60 to 100 feet. Very tenacious of life, the injured trees sprout anew from any part as readily as willows; yet, through the avarice and carelessness of man, they are rapidly disappearing. Timher, the well known light and durable "redwood." Leaves in two ranks, lanceolate, one-half inch long, poiuted; cones one-half to one inch long.

Big Tree.

Second species, *Sequoia gigantea*, Torr. "Big Tree," found only in about 20 groves on the western slope of the high Sierra, from Calaveras county to Fresno. All things considered, this is the largest tree in the known world. Some species of eucalypti in Australia are taller, and perhaps specimens may he found girting more at the swelled-out hase, hut they generally taper fast upward, have short limbs and very thin bark. The giant sequoia is often found 300 to 400 feet bigh, with a circuit at base of 80 to over 100 feet, the vast trunk but slightly tapering upward to the crown, where it suddenly divides into branches, being often found without a limb for 200 feet; its soft, reddish, thick, cedar-like bark deeply furrowed from top to bottom, giving the shafts the appearance of magnificent fluted columns propping their broad, shield-like crowns of light, gauzy foliage against the sky. Leaves on young trees acerose, one-half inch long; on limbs of matured trees reduced to pointed scales; cones the size of a hen's egg, hut knobby, without prickers, and composed of about 36 large pyramidal scales, their apexes eutering the elongated core of the cone, aud the interstices between them filled with 80 to 120 flat, winged seeds, resembling those of tbe common parsnip.

The big trees of California have justly been made the theme of glowing descriptions hy travelers, and hy scientists as well. The writer has published several articles in the PACIFIC RURAL PRESS and in Eastern journals, to which the reader is referred for elahorate descriptions, especially going to disprove their reputed great age of 3,000 to 4,000 years.

Washingtonia vs. Wellingtonia.

Before leaving the subject now, however, I wish to advert to a matter relating to the big trees, growing out of the pride I take in every noble product of my adopted State. I allude to the hahit the English have of misnaming our giant *Sequoia* by calling it "Wellingtonia." The history of its naming, re-naming and misnaming is substantially as follows: When first discovered in 1852 fragmentary specimens were sent to San Francisco and the East, and to England. Dr. Kellogg, of San Fraucisco, discovered what he took to be distiuguishing generic characters, and he very patriotically named the apparently new genus "Washingtonia." Dr. Lindly, the leading botanist of England, also pronounced (1853) the tree to he the type of a new genus, and joyfully called it "Wellingtonia." The two names were published to the world with descriptions of the tree about the same time, and scientists of the two countries rallied loyally to their standard bearer, shouting "Wellingtonia" or "Washiugtonia," as tbey happened to he on either side of the Atlantic. Meanwbile seeds had been sent abroad, where they readily grow, and English horticulturists distributed plants by the million over their vast Empire, thus disseminating their name world-wide. But a few months after Drs. Torrey and Gray, of New York; Endlicher of London, and De Caisne, of Paris, determined from fuller specimens that the wonderful tree belonged to an old well-established genus, the *Sequoia*, or redwood, and, as is the rule, most botanists at once adopted the proper name. But the name of "Wellingtonia" has got hold of the English mind (and pride), and while they are forced to say *Sequoia* when talking with American scientists, they cling tenaciously to the misnomer when talkiug with the uneducated, or with Englishmen who are willing to he unscientific rather than give up a name commemorating their Irou Duke.

Sir Joseph Hooker's Position.

I wrote recently to Sir Joseph Hooker, President of the Royal Society of England, and the most eminent botanist of the age, protestiug against the unscientific use of "Wellingtonia," and asking where he allowed the weigbt of his great influence to rest. I woke up a full-blooded Englishman. Hear him:

"Wellingtonia" is a misnomer in a scientific sense," he replies, "hut not in a vernacular sense. The name "Wellingtonia" is rooted as deep in Englaud and Europe as the "hig tree" in its California soil, and the people of England and Europe who know the hig tree only hy the name of "Wellingtonia" are as numerous as the leaves on the biggest *Sequoia*. Colloquial languages are means, not ends, and the conveniences of the day and hour will carry the day in the face of all argument and all science. It is only wisdom to accept the inevitable. You might as well attempt to restore the Dutch name of New York to the American vernacular as to force "Sequoia" upon the English and continental vernacular. After all, what does it matter," he concludes (very much, I say,) "the botanist knows that *Sequoia* is the right name, hut the uneducated know only "Wellingtonia." That serves the purpose. To him one name is as good as another," (not so, my English special pleader,) "and 'first come, first served,' is his motto."

Rebuttal.

Now it happens that some English so-called scientific works, like "Gordon's Pinetum" and the like, describe the big tree under the name of "Wellingtonia," used, not as the vernacular or common name, hut as the botanical or scientific name, admitting in the same paragraph that the genus is not well founded, yet persisting in keeping it up, encouraged thereto no douht by the quasi endorsement of such eminent authority as Hooker. Our botanical hooks and records abound in cases similar to this of the *Sequoia*, *i. e.*, where a plant has been called by a certain name until familiar and adopted into the vernacular, but wider research and better instruments for examination have compelled in time a change of name hy competent authority, and all persons are expected to yield to the dictum, whatever tbeir preferences. This is correct, scientific procedure. If it were not so there would he an end to all improvement, all advancemeut, in a word, to all science; and the predileotions of no clans, people or nations should he allowed to stand in the way of scientific facts. As well might we Americans, preeminently entitled to our pride in commemorating the "Father of bis Country," he still clamoring for "Washingtonia," because our botanist first described and named it such. But no, it is characteristic of Americans to correct abuses before tbey become "inevitable." I know that Sir Joseph means to be fair and honest, but I doubt if he would acquiesce so readily in his "inevitable" if he were not an Englishman. As I am an American, born on tbe same soil with the hig trees, I would rather that Americans reject this English misnomer, and promptly call our famous trees by their proper name of "Big Trees," or by their botanical name of *Sequoia gigantea*.

[To be Continued.]

Igneous Meteors.—No. 1.

[Written for the MINING AND SCIENTIFIC PRESS.]

Ærolites, Fire-Balls, Shooting-Stars.

Igneous meteors are luminous bodies whicb suddenly appear in the sky, usually at a great bight above the surface of the earth, and sboot across the heavens with immense velocity, and are sometimes accompanied with the fall of meteoric stones or ærobtes. As regards meteoric stones, it is evident that the striking phenomena attending tbeir fall upon thc earth—the hrilliant luminous display, the violent detonations, the tremeudous momentum with which the hot masses bury themselves in the ground—were well calculated to arrest the attention, and to stimulate the imagination of mankind in all periods of bistory. We find, accordiugly, that these hodies have been observed to fall in all ages of the world. Probably the earliest account we have of any one of them is to be found recorded in Joshua, chap. 10, verse 11; "at any rate, the phenomenou referred to in that verse can he interpreted by reference to some of the more modern falls of meteoric stones."

One of the most remarkable falls recorded in ancient history is that of the Thracian stone, mentioned by Pliny in chapter 58 of Second Book on Natural History. It fell near Ægospotamos, in Thrace, about 467 years hefore the Christian era. He describes it as being of a burnt color, and as heing held in veneration by the inhabitants of the country. This is probahly the stone which Anaxagoras, tbe Clazomenian philosopher, predicted, it is said, would one day fall from tho sun. In Butler's "Hudibras" this event is thus noticed.

> "For Anaxagoras long agone
> Saw hills, as well as you i' th' moon;
> And held the sun was but a piece
> Of red-hot iron, as big as Greece;
> Believ'd the heav'ns were made of stone,
> Because the sun had voided one:
> And, rather than he would recant
> Th' opinion, suffered banishment."

Some persons think, with appareutly very good reason, that the image which fell down from Jupiter, and was worshipcd by the Ephesians, (referred to in Acts, chap. 19, verse 35,) was a meteoric stone. Another ancieut and memorable ærolite is now at Mecca; for the celebrated black stone, *Hajar el Aswad*, that forms an ohject of adoration of the pilgrims to thc Kaaba, at Mecca, is doubtless one of these bodies.

Varieties of Igneous Meteore.

At one period it was a question among scientific men whether ærolites, fire-balls and shooting-stars constitute a single class of igneous meteors. Shooting-stars are of all degrees of size and hrightuess, and some occur which exceed Jupiter or Venus, or even the moon in hrilliancy. In some of them the globular form can be easily recognized; these are, in every respect, similar to fire-balls or *bolides*. In fact, it is impossible, from their appearance, to make any distinction hetween the larger shooting-stars and the smaller so-called fire-halls. Again, the larger fire-balls often explode into fragments, the parts scattering across the sky in different directions. In some cases, terrific detonations are heard over an extensive region of country a short time after the visible explosion; and, at times, from these detonating meteors stouy fragments come down, scattering themselves over a region of many miles in extent, and frequently striking the ground with sufficient velocity to bury themselves two or more feet deep. These fragments constitute ærolites or meteoric stones. Hence, modern physicists are disposed to regard all of tbese igneous meteors as having a similar origin and character, though differing in size, in color, in hrightness, in chemical composition, etc. Additional evidence of the correctness of this conclusiou is derived from the hight and velocity of all kinds of igneous meteors.

Hight.

By stationing two observers 50 or 100 miles apart, to observe and record the track of the same ærolite, fire-hall, or shooting-star, as it is projected from the different points of observation on different parts of the sky, the actual altitude of these igneous meteors can be determined with more or less precision. The observations of Brandes, of Leipsic; Benzenberg, of Dusseldorf; Wartmann, of Switzerland; Newton, of New Haven, and others, have thus determined their hight to vary from 15 to 140 miles from the surface of the earth. When the larger fire-halls come lower down than 30 miles they usually send down fragments to the surface of the earth.

Velocity.

From the angular extent of the track of the igneous meteor, the time of its transit, and its distance from the observer, it is easy to determine the velocity of its motion. For meteoric stones, the observations of Glaisher, Petit, Daubree, and others, indicate that tbese bodies traverse our atmospbere with velocities varying from four to forty miles per second. With respect to shooting-stars, the observations of Benzenberg, Quetelet, Herrick, Newton, and others, assign to them velocities fully equal to, if not surpassing, the velocities of meteoric stones. Estimating their mean velocity at about 30 miles per second, it is evident that it far surpasses the speed of any terrestrial motion, being more than 100 times the initial velocity of a cannon ball. Tbe bigher velocities assigned to shooting-stars, as compared with meteoric stones, probably arises from the circumstance that the smaller meteoric masses on entering the upper and highly attenuated atmosphere of the earth, are dissipated and volatilized before their motion is greatly retarded hy the resistance of the air; while the larger masses, constituting ærolites, descending into the denser strata of the atmospherc, encounter such an enormous resistance as to vastly reduce tbeir velocities before reaching the surface of the earth. Hence it is quite possible that the various varieties of igneous meteors may enter our atmosphere with approximately similar velocities, but that tbe subsequent retarding influence of the resistance of the air creates inequalities of speed, which manifests itself more especially in the larger masses traversing the lower strata of the atmosphere.

Luminous Traine.
